Last time

- Authentication (MAC) using shared keys
- Getting MACs from PRFs

Today

- How to combine CPA security + MACS:
- Security against active attacks (CCA security)

Authentication:

How would Bob know Alice sent this message?

Strong MAC = for all (m, k) there is a unique acceptable t / Last time
 $t = F_k(m)$

Formal definition of security

The message authentication experiment $\text{Mac-forge}_{\mathcal{A}, \Pi}(n)$:

1. A key k is generated by running $\text{Gen}(1^n)$.
2. The adversary \mathcal{A} is given input 1^n and oracle access to $\text{Mac}_k(\cdot)$. The adversary eventually outputs (m, t) . Let \mathcal{Q} denote the set of all queries that \mathcal{A} asked to its oracle.
3. \mathcal{A} succeeds if and only if (1) $\text{Vrfy}_k(m, t) = 1$ and (2) $m \notin \mathcal{Q}$. In that case the output of the experiment is defined to be 1.

Game

ADV can NOT find (m, t') $t' \neq t$ that $\text{Vrfy}(m, t')$.

Def

DEFINITION 4.2 A message authentication code $\Pi = (\text{Gen}, \text{Mac}, \text{Vrfy})$ is existentially unforgeable under an adaptive chosen-message attack, or just secure, if for all probabilistic polynomial-time adversaries \mathcal{A} , there is a negligible function negl such that:

$$\Pr[\text{Mac-forge}_{\mathcal{A}, \Pi}(n) = 1] \leq \text{negl}(n).$$

Constructing MACs using PRFs

- Suppose $F_k(\cdot)$ is a PRF with key, input, output lengths: $n, *, \ell$
- How do we generate MAC tags for messages?

- To tag message m , attach $t = F_k(m)$ to it.

$$\ell = \lg^2(n) \rightarrow 2^{-\ell} = 2^{-\lg^2(n)} = \frac{1}{n^{\lg(n)}}$$

- The proof needs $\frac{1}{2^\ell}$ to be smaller than any $\text{poly}(n)$. We can let $\ell = n$

Block-cipher / AES, DES

What we have achieved.

- CPA-secure encryption based on PRFs.
 - Randomized.
 - Needs input of PRF to be large enough.

Pick r

$$Enc_k(m) \rightarrow [r, F_k(r) \oplus m]$$

- MACs for authentication based on PRFs.
 - Deterministic
 - Needs output of PRF to be large enough.

$$MA_k(m) = t = F_k(m).$$

PRFs could be obtained from:

- Theory: PRGs and even one-way functions
- Practice: Any "good" cryptographic hash function.

PRF

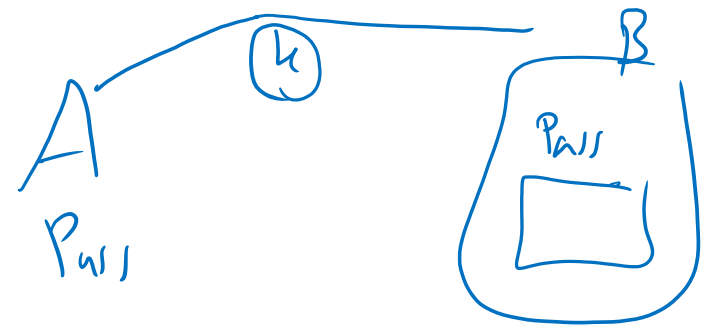

String Concatenation

$$H(k, x) = F_k(x)$$

Chosen cipher-text security:

- Combining CPA security with MACs to handle active attacks.

Password verification example

- Alice (client) wants to login on Bob's computer (server)

- Alice's browser has a shared key k with Bob
- Alice encrypts the password $pass$ using k and sends $c = \text{Enc}_k(pass)$
- Bob decrypts c and if the password is correct it allows Alice to login.

$$pass = b_1 \text{ --- } b_{100}$$

we just need 100 tries to recover it.

- Issue: the fact that there is a "feedback" to modified messages given to "Alice" (or an adversary) might lead to recovering the full $pass$

CPA secure Enc could be "resettable": there might be $\text{Res}(c, i, b) \rightarrow c$ $m = m_1 \text{ --- } m_k$
 $\rightarrow \text{Dec}(c') \rightarrow m_1, m_2, \dots, m'_i = \dots m_k$

Idea: stronger security

- Hope: if c is an encryption, make any modification of c "useless".

$$\text{Enc}(\overset{n}{k}, \overset{l}{m}, r) \rightarrow c$$

$$\text{Dec}(k, c) \rightarrow m'$$

Correctness: $\forall k, \forall m, \forall r :$

$$\text{Enc}(k, m, r) \rightarrow c$$

$$\text{Dec}(k, c) \rightarrow m'$$

$$m = m'$$

Specific symbol: \perp

how we encrypted

$n+l$ bits
 2^{n+l}

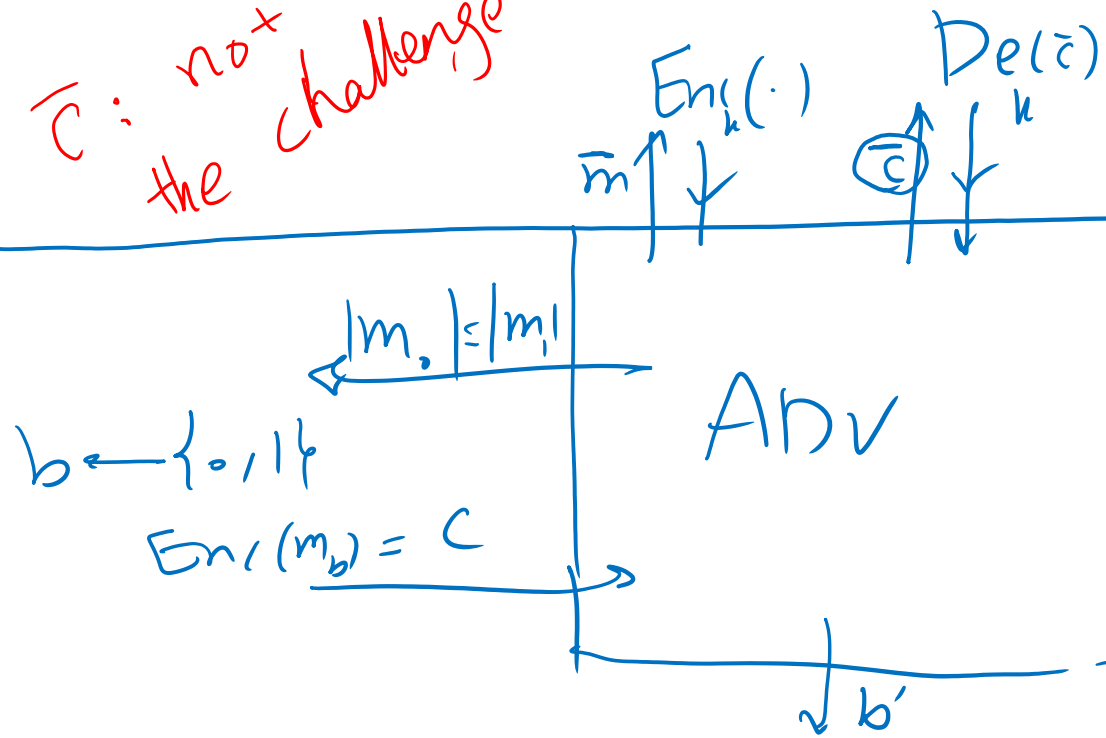

if we somehow encrypt by $2n+l$

2^{l+2n}

↓ not decryptable!

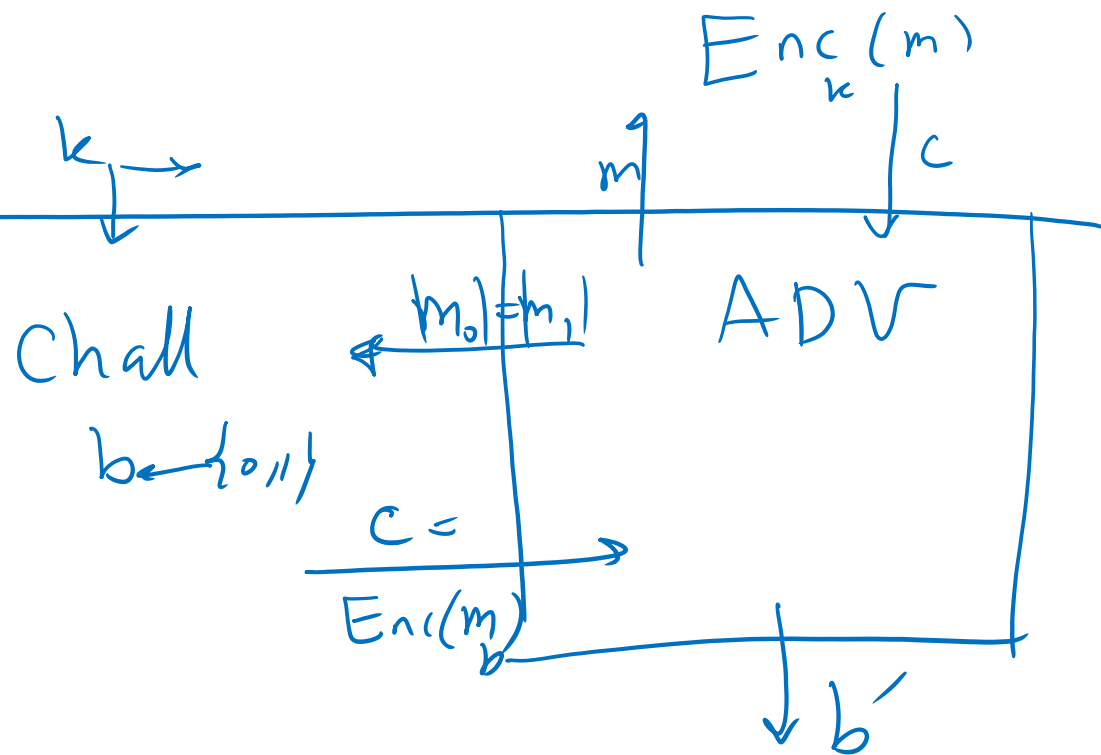

Defining CCA security (in contrast with CPA)

\bar{c} : not the challenge

$$\Pr[\text{Win}] \leq \frac{1}{2} + \text{negl}(\cdot)$$

$\text{Win} := \{b' = b \mid c \in Q_c\}$ where $Q_c = \{\text{ciphertext queries by Adv}\}$

$$\Pr[\text{Win}] \leq \text{negl}(\cdot) + \frac{1}{2}$$

$\text{Win} := \{b' = b\}$

Exercise

- If $S=(\text{Enc},\text{Dec})$ is CCA secure, then using scheme S for the application of encrypting passwords will be “safe” (will need to formalize it).
- Note: the specific attack we discussed does not work anymore if we use CCA secure: if one can “fix” the i 'th bit to zero, it is NOT CCA secure
- More generally: if adversary modifies the ciphertext in any way, the decryptor will reject and output “error”.

CPA security + MAC to \rightarrow CCA security

PRF

- We have:
- CPA-secure encryption: (Enc, Dec) based on key k_1
- Strongly-secure MAC: (Mac, Vrf) – based on key k_2

$(\text{CPA sec of } S_1) \wedge (\text{Strong MAC-sec of } S_2) \rightarrow \text{CCA sec of } S_3$

- We want:
- CCA secure encryption : (ENC, DEC)

What are most "natural" ways to do it?

① Authenticate then encrypt

$$m \rightarrow \underbrace{(m, t_m)}_{m'} \rightarrow \text{Enc}(m')$$

two ways

② Encrypt then Authenticate.

$$m \rightarrow \text{Enc}(m) \rightarrow (c, t_c)$$

③ do both:

$$m \xrightarrow{\text{Enc}}$$

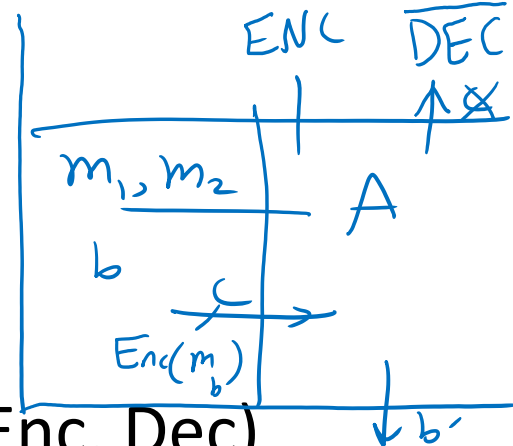

most natural

Dec(c):

- ① get $m = \text{Dec}(k_1, c)$
- ② $\text{verif}(k_2, m, t_m)$:
 - if Passes \rightarrow output m
 - oth $\rightarrow \perp$

CPA security + MAC to \rightarrow CCA security

1st (wrong) try

- Suppose k_1 is key for MAC and k_2 is key for CPA scheme (Enc, Dec)
- We want to encrypt message m

- First generate a tag using MAC: $t = \text{MAC}_{k_1}(m)$
- Encrypt both of $[m, t]$ and get $C = \text{Enc}_{k_2}([m, t])$

ENC

both cases $C \neq C$

hint:

- To decrypt: First get back $[m, t]$ using $\text{Dec}_{k_2}(C)$

CPA-secure but is also verifiable.

- Then run $\text{Verify}_{k_1}(m, t)$ and output \perp if it rejects... otherwise output m

if $m_0 = 000$
 $m_1 = 111$

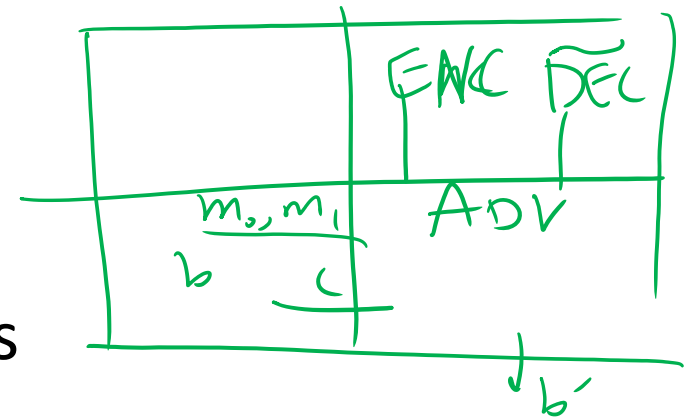

reset first bit of $m \rightarrow m'$
 $000 \rightarrow 000$
 $011 \rightarrow \perp$

CPA security + MAC to \rightarrow CCA security

2st (correct) way:

- ENG
- First encrypt and then authenticate
 - $c = \text{Enc}_{k_2}(m)$ and $tag = \text{MAC}_{k_1}(c)$ and send $C = [c, tag]$

- Decryption:
- First run $\text{Verify}_{k_1}(c, t)$ and output \perp if it rejects
- If verify passes: then decrypt c using k_2 to get m and output it

Intuition: proving $\overline{\text{DEC}}$ is useless ...
we will be back to CPA Security!

Proof of security (bit picture)

Construction $\overbrace{ENC, DEC}^S$. Sec-game CCA-sec

2 - Assumptions: $\left\{ \begin{array}{l} \underbrace{(ENC, DEC)}_{S_1} \text{ --- CPA-sec} \\ \underbrace{(MAC, Ver)}_{S_2} \text{ --- Strongly sec.} \end{array} \right.$

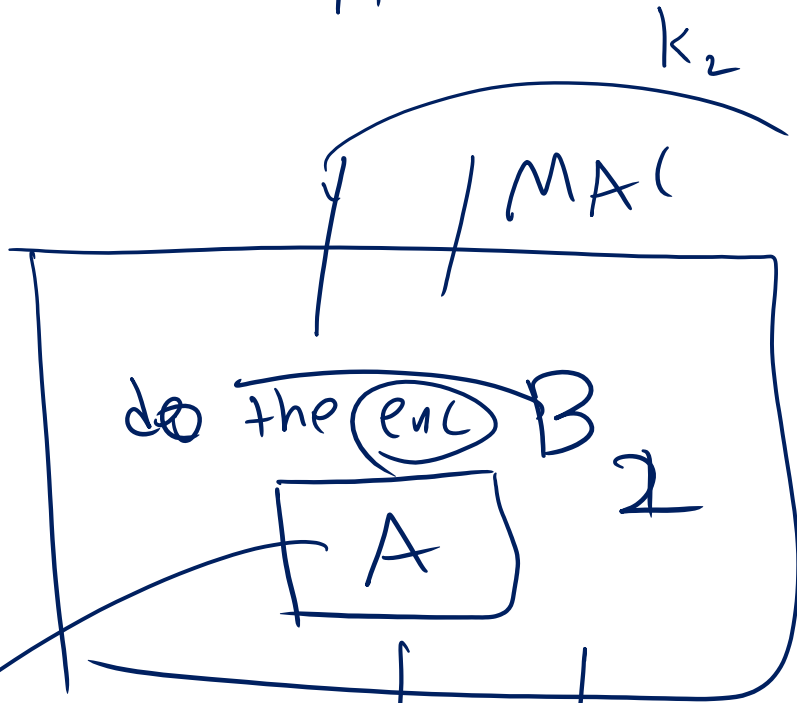

if A is a poly time attacker against S winning by non-neg ϵ

\exists either of these $\left\{ \begin{array}{l} \exists B_1 \text{ poly-time against } S_1 \text{ win } \geq \epsilon_1 \\ \exists B_2 \text{ poly-time against } S_2 \text{ win } \geq \epsilon_2 \end{array} \right.$

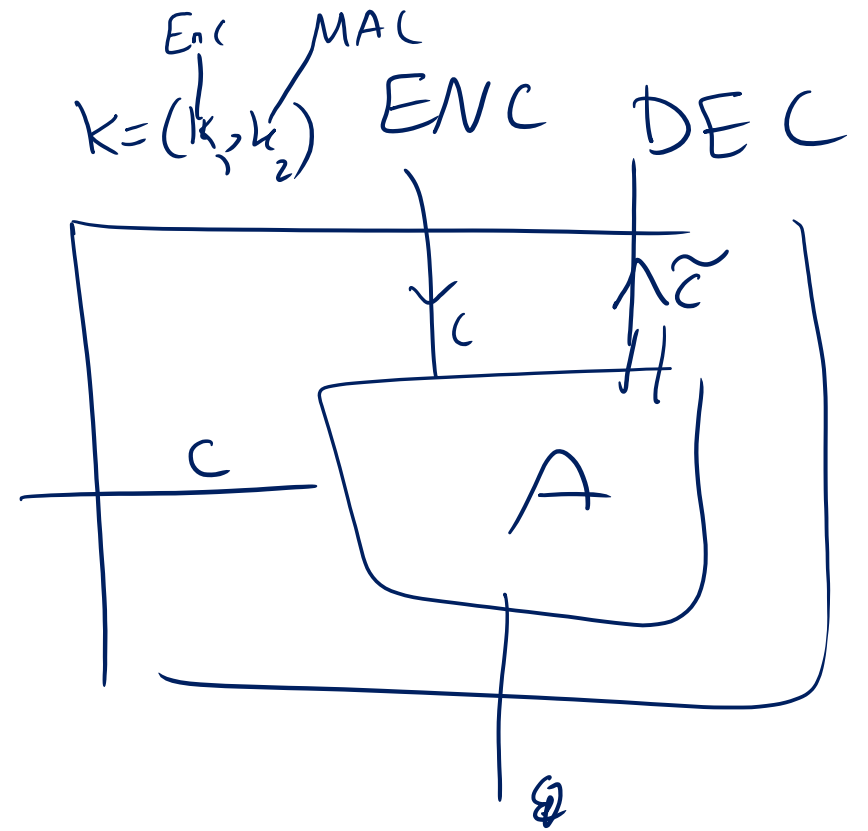

α Condition: ADV asks some \tilde{c} to $DEC(\tilde{c})$ that was not given to him.

Proof of security (breaking MAC)

if α happens.

Simulate environment for (A)

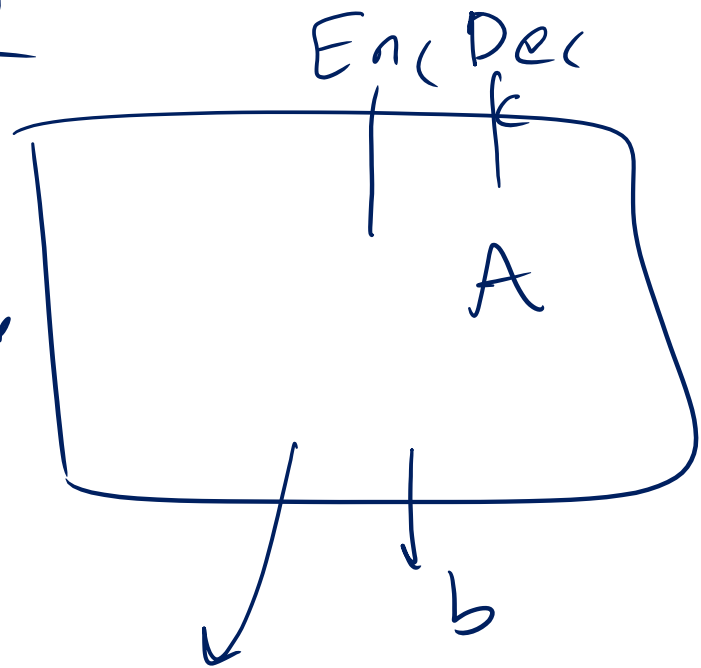

(\tilde{m}, \tilde{t}) pass the verif.

Proof of security (breaking CPA security)

\mathcal{A} does NOT happen

P_1 | A asking \tilde{c} that Decrypts
but \tilde{c} not given to A

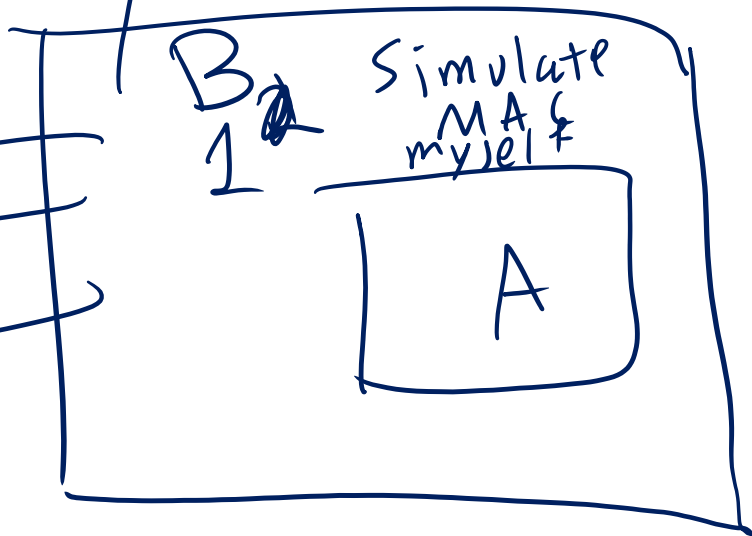

$\epsilon/2$

only enc oracle.

CPA

sec.

game:

win

without

asking

such \tilde{c}

$$\geq \epsilon - \frac{\epsilon}{2} \geq \frac{\epsilon}{2}$$
