

Generalized Numbers

Theorem: some real numbers are not finitely describable!

Theorem: some finitely describable real numbers are not computable!

Problem: Solve the following equation for X:

$$X^{X^{X^{X^{\dots}}}} = 2 \Rightarrow X^2 = 2 \Rightarrow X = \sqrt{2}$$

where the stack of exponentiated x's extends forever.

This “power tower” **converges** for:

$$0.065988 \approx e^{-e} < X < e^{1/e} \approx 1.444668$$

Generalization to complex numbers:

Problem: Given any five points in/on the unit square, is there always a pair with distance $\leq \frac{1}{\sqrt{2}}$?

- What approaches fail?
- What techniques work and why?
- Lessons and generalizations

Problem: Given any five points in/on the unit equilateral triangle, is there always a pair with distance $\leq \frac{1}{2}$?

- What approaches fail?
- What techniques work and why?
- Lessons and generalizations

Math phobic's nightmare

Historical Perspectives

George Boole (1815-1864)

- Mathematician and philosopher
- Invented symbolic / **Boolean logic**
- Invented **Boolean algebra**, i.e. “calculus of reasoning”
- A **founder of computer science**
- “An Investigation into the Laws of Thought”
- **Influenced** De Morgan, Schröder, Shannon
- All modern computers, electronics, phones, data transmission, rely on **Boolean principles**

GEORGE BOOLE
 LL.D. D.C.L. F.R.S.
 1815 - 1864
 GEORGE BOOLE, FATHER OF MODERN ALGEBRA, AUTHOR OF THE LAWS OF THOUGHT AND FIRST PROFESSOR OF MATHEMATICS AT UNIVERSITY COLLEGE, CORK, WAS BORN IN LINCOLN AND ESTABLISHED AN ACADEMY IN THIS HOUSE C. 1810.

BINARY LETTER FROM GRANDMA

Mozart writing the digital version of his symphony No. 38 in D major.

Historical Perspectives

Augustus De Morgan (1806-1871)

- Mathematician and logician
- Developed logic & mathematical induction
- De Morgan's Laws in logic & set theory
- Invented relational algebra
- Corresponded extensively with Hamilton
- Influenced Russell, Whitehead, and Tarski
- Studied paradoxes

Historical Perspectives

Charles Babbage (1791-1871)

- Mathematician, philosopher, inventor, mechanical engineer, and economist
- The **father of computing**
- Built world's **first mechanical computer**
 - the “**difference engine**” (1822)
- Originated the **programmable computer**
 - the “**analytical engine**” (1837)
- Worked in **cryptography**
- Developed **Babbage's principle** of division of labor

Babbage's Difference Engine

- World's **first mechanical computer**
- Designed in **1822**, redesigned in 1847-1849
- **25,000 parts**, 15 tons, 8ft tall, 31 digits of precision
- Tabulated polynomial functions, used **Newton's method**
- **Approximated** logarithmic and polynomial functions
- Used **decimal number system** and hand-crank

Babbage's Difference Engine

Babbage's difference engine built from Mechano and Lego

Babbage's Analytical Engine

- World's **first general-purpose computer**
- Designed in **1837**, redesigned throughout Babbage's life
- **Turing-complete**, memory: 1000x50 digits (21 kB)
- **Fully programmable** "CPU", used punched cards
- Featured **ALU**, "**microcode**", **loops**, and **printer!**
- Could **multiply** two 20-digit numbers in **3 min**
- Few components built by Babbage; constructed in 1991

WELCOME TO THE CHARLES BABBAGE INSTITUTE

The Charles Babbage Institute (CBI) is an archives and research center dedicated to preserving the history of information technology and promoting and conducting research in the field.

Primary support for CBI is provided by the University of Minnesota, through the Institute of Technology and the University Libraries. Additional support is provided by corporate donors and individuals through the Friends of CBI.

SPOTLIGHT

- May 20th MHHC: IBM's Blue Gene
- New CBI Newsletter (Spring 2009, Vol. 31:1)
- McDonald Named 2009-2010 Tomash Fellow
- 2009 Norberg Travel Award Recipients

THE CBI ARCHIVES

The CBI Archives collects, preserves and provides access to rich archival collections and rare publications documenting the history of technology. Detailed archival finding aids are available. Researchers can also access digitized images (Burroughs Corporation Image Database) and one of the world's largest collections of research grade oral history interviews (CBI Oral History Database) through the CBI Web site. [More »](#)

THE CBI RESEARCH PROGRAM

CBI's historical research program identifies areas in which to collect archival materials; fosters new understanding of developments in the history of computing, software, and networking; supports the work of scholars outside the Institute (Tomash Fellowship and Norberg Travel Grant); and works collaboratively with individuals and organizations throughout the world. Lovelace Medal

The Lovelace Medal is presented to individuals who have made a contribution which is of major significance in the advancement of Information Systems or which adds significantly to the understanding of Information Systems.

About the medal

Lovelace Medal 2009

2009 winner
The winner of the 2009 Lovelace Medal is Professor Yorick Wilks.

Previous Lectures

Video: A tribute to Karen Spärck Jones
The 2008 BCS Lovelace Medal lecture was a very special event dedicated to the memory of Karen Spärck Jones who was presented the award just weeks before she died last year. The lecture was delivered by Dr Ann Copestake and is now available to watch online.

2007 Lovelace Lecture - Sir Tim Berners-Lee
The Web is a technical and social creation, dependent on both technical protocols and social conventions. The origins and potential futures of this large scale, emergent phenomena were discussed by Sir Tim Berners-Lee in this year's BCS Lovelace Lecture - now available to watch via this website.

Previous winners

- Previous winners** of the Lovelace Medal have included:
- 2008 - Dr Tony Storey
 - 2007 - Karen Sparck-Jones
 - 2006 - Sir Tim Berners-Lee
 - 2005 - Dr Nicholas McKeown

Ada Lovelace notes on “Sketch of the Analytical Engine Invented by Charles Babbage”, by L. F. Menabrea, 1843

Her notes (three times longer than the paper itself!) contain the world’s first computer program (for calculating Bernoulli numbers):

Number of Operations Nature of Operations		Variables for Data						Working Variables									Variables for Results	
		¹ V ₀	¹ V ₁	¹ V ₂	¹ V ₃	¹ V ₄	¹ V ₅	⁰ V ₆	⁰ V ₇	⁰ V ₈	⁰ V ₉	⁰ V ₁₀	⁰ V ₁₁	⁰ V ₁₂	⁰ V ₁₃	⁰ V ₁₄	⁰ V ₁₅	⁰ V ₁₆
		+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+	+
		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
		m	n	d	m'	n'	d'										$\frac{dn' - d'n}{mn' - m'n} = x$	$\frac{d'm - dm'}{mn' - m'n} = y$
1	×	m	n'	mn'										
2	×	n	m'	$m'n$										
3	×	d	dn'									
4	×	0	d'	$d'n$									
5	×	0	0	$d'm$								
6	×	0	0	dm'							
7	-	0	0	$(mn' - m'n)$						
8	-	0	0	$(dn' - d'n)$					
9	-	0	0	$(d'm - dm')$				
10	÷	$(mn' - m'n)$	0	$\frac{dn' - d'n}{mn' - m'n} = x$		
11	÷	0	0	$\frac{d'm - dm'}{mn' - m'n} = y$	

Quotes from the Ada Lovelace notes on

“Sketch of the Analytical Engine Invented by Charles Babbage”, 1843

“We may say most aptly, that the Analytical Engine *weaves algebraical patterns* just as the Jacquard-loom weaves flowers and leaves.”

“Again, it might act upon *other things besides number*, were objects found whose mutual fundamental relations could be expressed by those of the *abstract science of operations*, and which should be also susceptible of adaptations to the action of the operating *notation* and mechanism of the engine. Supposing, for instance, that the fundamental relations of pitched sounds in the science of harmony and of musical composition were susceptible of such expression and adaptations, the engine might compose elaborate and scientific pieces of *music of any degree of complexity or extent.*”

Quotes from the Ada Lovelace notes on

“Sketch of the Analytical Engine Invented by Charles Babbage”, 1843

“Many persons who are not conversant with mathematical studies, imagine that because the business of the engine is to give its results in *numerical notation*, the *nature of its processes* must consequently be *arithmetical* and *numerical*, rather than *algebraical* and *analytical*. This is an error. The engine can **arrange and combine** its numerical quantities exactly **as if they were *letters* or any other *general symbols***; and in fact it might bring out its results in algebraical *notation*, were provisions made accordingly.”

“But it would be a **mistake** to suppose that because its *results* are given in the *notation* of a more restricted science, its *processes* are therefore **restricted to those of that science**. The object of the engine is in fact to give the *utmost practical efficiency* to the resources of *numerical interpretations* of the **higher science of analysis**, while it uses the processes and combinations of this latter.”

VOGUE
DIRETTORE DI VITA

*alice in
wonderland*

*Levi's Carroll dressed her as an innocent in satin and ribbons.
Disney made her flatter haired and saucer eyed.
In the pages of Vogue the land of merry sublimity and late-raining
rabbits slimmers to the again - on the world's most influential
designers dress the original little girl lost in their own visions.*

Photographed by Annie Leibowitz

Alice and the White Knight: A Lesson in Logic, Semantics, and Pointers

`You are sad,' the Knight said in an anxious tone: `let me sing you a song to comfort you.'

`Is it very long?' Alice asked, for she had heard a good deal of poetry that day.

`It's long,' said the Knight, `but it's very, *very* beautiful. Everybody that hears me sing it -- either it brings the *tears* into their eyes, or else --'

logical disjunction!

`Or else what?' said Alice, for the Knight had made a sudden pause.

law of the excluded middle!

`Or else it doesn't, you know. The name of the song is called "*Haddocks' Eyes*".'

pointer to a pointer!

`Oh, that's the name of the song, is it?' Alice said, trying to feel interested.

`No, you don't understand,' the Knight said, looking a little vexed. `That's what the name is *called*. The name really is "*The Aged Aged Man*".'

pointer dereferencing: meta-pointer resolved!

`Then I ought to have said "That's what the *song* is called"?'`

Alice corrected herself. separation of abstractions: variable vs. pointer!

`No, you oughtn't: that's quite another thing! The *song* is called "*Ways and Means*": but that's only what it's *called*, you know!'

call-by-name vs. call-by-value!

`Well, what *is* the song, then?' said Alice, who was by this time completely bewildered.

`I was coming to that,' the Knight said. `The *song* really is "*A-sitting On a Gate*": and the tune's my own invention.'

All about Alice

Alice is an innovative 3D programming environment that makes it easy to create an animation for telling a story, playing an interactive game, or a video to share on the web. Alice is a teaching tool for introductory computing. It uses 3D graphics and a drag-and-drop interface to facilitate a more engaging, less frustrating first programming experience.

[Read more...](#)

Teaching Materials

Alice is a teaching tool designed as a revolutionary approach to teaching and learning introductory programming concepts. The Alice team has developed instructional materials to support students and teachers in using this new approach. Resources include textbooks, lessons, sample syllabuses, test banks, and more. Other authors have generously joined our efforts, creating additional textbooks.

Historical Perspectives

Georg Cantor (1845-1918)

- Created modern set theory
- Invented **trans-finite** arithmetic (highly controversial at the time)
- Invented **diagonalization** argument
- First to use **1-to-1 correspondences** with sets
- Proved **some infinities “bigger”** than others
- Showed an **infinite hierarchy of infinities**
- Formulated **continuum hypothesis**
- **Cantor’s theorem**, “**Cantor set**”, Cantor dust, Cantor cube, Cantor space, **Cantor’s paradox**
- Laid foundation for **computer science theory**
- **Influenced** Hilbert, Godel, Church, Turing

Requires [windows media player](#) or [real player](#).

synopsis

There was once a hotel in the mountains that was so popular with guests, the Manager decided to extend it. Yet still it remained full. The Manager continued to extend it, until eventually it became infinitely large. One day much to his surprise, no spare rooms could be found in his now infinite hotel. All the mathematical calculations, which he normally relied on to find the rooms, just wouldn't work...

Problem: Are there more integers than natural #'s?

$$\mathbb{N} \subset \mathbb{Z}$$

$$\mathbb{N} \neq \mathbb{Z}$$

So $|\mathbb{N}| < |\mathbb{Z}|$?

Rearrangement:

Establishes 1-1
correspondence

$$f: \mathbb{N} \leftrightarrow \mathbb{Z}$$

$$\Rightarrow |\mathbb{N}| = |\mathbb{Z}|$$

Problem: Are there more rationals than natural #'s?

$\mathbb{N} \subset \mathbb{Q}$

$\mathbb{N} \neq \mathbb{Q}$

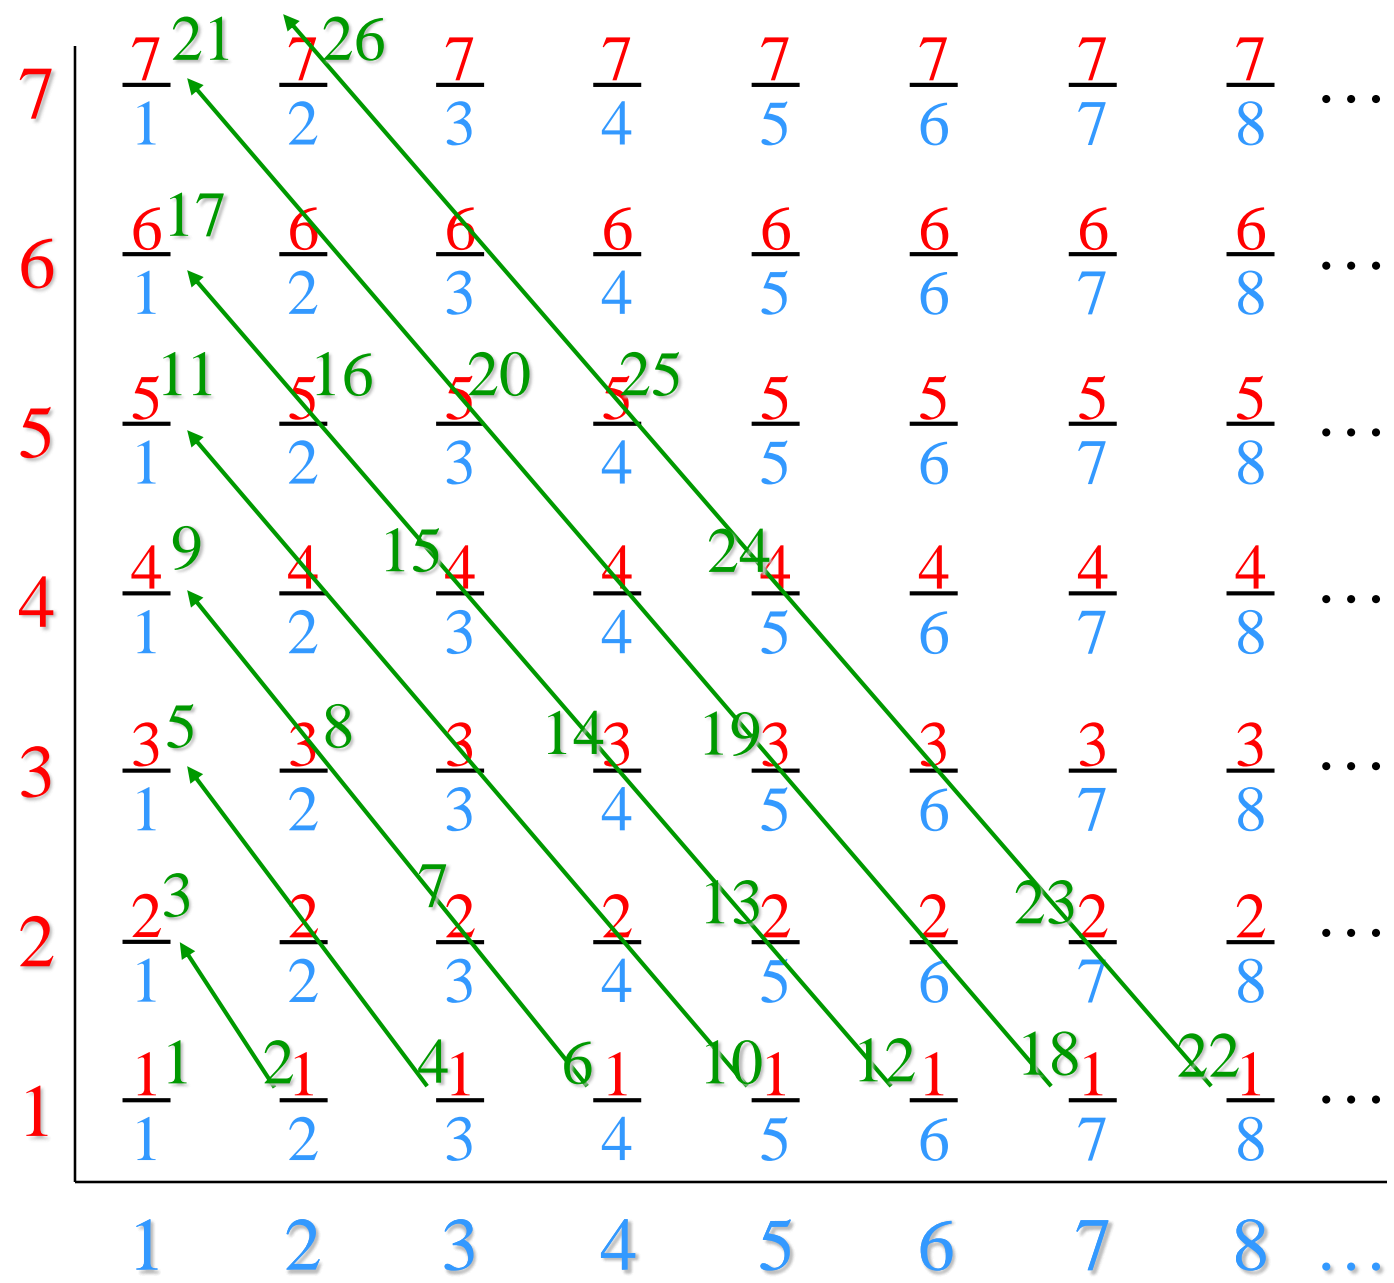

So $|\mathbb{N}| < |\mathbb{Q}|$?

Dovetailing:

Establishes 1-1
correspondence

$f: \mathbb{N} \leftrightarrow \mathbb{Q}$

$\Rightarrow |\mathbb{N}| = |\mathbb{Q}|$

Problem: Why doesn't this "dovetailing" work?

There's no
"last" element
on the first line!

So the 2nd line
is never reached!

⇒ 1-1 function
is not defined!

Dovetailing Reloaded

Dovetailing: $f: \mathbb{N} \leftrightarrow \mathbb{Z}$

-4	-3	-2	-1	0	1	2	3	4
----	----	----	----	---	---	---	---	---

\mathbb{Z}

\mathbb{N} 1 2 3 4 5 6 7 8 9

To show $|\mathbb{N}| = |\mathbb{Q}|$ we can construct $f: \mathbb{N} \leftrightarrow \mathbb{Q}$ by sorting x/y by increasing key $\max(|x|, |y|)$, while avoiding duplicates:

$\max(|x|, |y|) = 0 : \{0\}$

$\max(|x|, |y|) = 1 : 0/1, 1/1$

$\max(|x|, |y|) = 2 : 1/2, 2/1$

$\max(|x|, |y|) = 3 : 1/3, 2/3, 3/1, 3/2$

... {finite new set at each step}

- Dovetailing can have many disguises!
- So can diagonalization!

Theorem: There are more reals than rationals / integers.

Proof [Cantor]: Assume a 1-1 correspondence $f: \mathbb{N} \leftrightarrow \mathbb{R}$ i.e., there exists a table containing all of \mathbb{N} and **all** of \mathbb{R} :

\mathbb{N}	\mathbb{R}
$f(1) =$	3 . 1 4 1 5 9 2 6 5 3 ...
$f(2) =$	1 . 0 0 0 0 0 0 0 0 0 ...
$f(3) =$	2 . 7 1 8 2 8 1 8 2 8 ...
$f(4) =$	1 . 4 1 4 2 1 3 5 6 2 ...
$f(5) =$	0 . 3 3 3 3 3 3 3 3 3 ...
...	...

$$X = 0.21934\dots \in \mathbb{R}$$

But X is missing from our table! $X \neq f(k) \forall k \in \mathbb{N}$

$\Rightarrow f$ not a 1-1 correspondence

\Rightarrow contradiction

$\Rightarrow \mathbb{R}$ is not countable!

There are more reals than rationals / integers!

Diagonalization Nonexistence proof!

Problem 1: Why not just insert X into the table?

Problem 2: What if $X=0.999\dots$ but $1.000\dots$ is already in table?

\mathbb{N}	\mathbb{R}
$f(1) =$	3 . 1 4 1 5 9 2 6 5 3 ...
$f(2) =$	1 . 0 0 0 0 0 0 0 0 0 ...
$f(3) =$	2 . 7 1 8 2 8 1 8 2 8 ...
$f(4) =$	1 . 4 1 4 2 1 3 5 6 2 ...
$f(5) =$	0 . 3 3 3 3 3 3 3 3 3 ...
...	...

$X = 0.21934\dots \in \mathbb{R}$

Diagonalization Nonexistence proof!

- Table with X inserted will have X' **still missing!**
Inserting X (or any number of X's) will not help!
- To enforce **unique table values**, we can avoid using 9's and 0's in X.

Celebrity Cruises **X** a true departure

**WELCOME
TO
INFINITY**

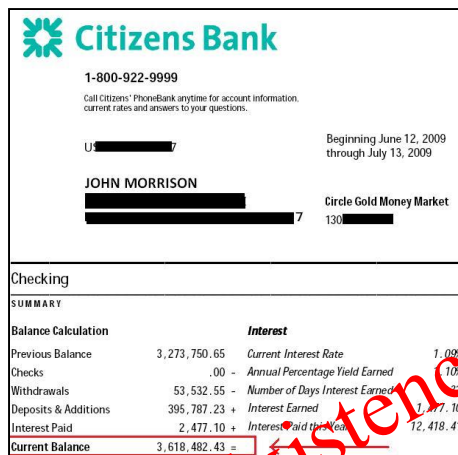

Infinity

Non-Existence Proofs

- Must cover all possible (usually infinite) scenarios!
- Examples / counter-examples are not convincing!
- Not “symmetric” to existence proofs!

Ex: proof that you are a millionaire:

“Proof” that you are not a millionaire ?

Existence proofs can be easy!

Non-existence proofs are often hard!

$P \neq NP$

Cantor set:

Start with **unit segment**

- Remove (open) **middle third**
- **Repeat recursively** on all remaining segments
- Cantor set is all the **remaining points**

Total **length** removed: $1/3 + 2/9 + 4/27 + 8/81 + \dots = 1$

Cantor set **does not contain any intervals**

Cantor set is **not empty** (since, e.g. interval endpoints remain)

An **uncountable number of non-endpoints** remain as well (e.g., $1/4$)

Cantor set is **totally disconnected** (no nontrivial connected subsets)

Cantor set is **self-similar** with Hausdorff dimension of $\log_3 2 = 1.585$

Cantor set is a **closed**, totally bounded, **compact**, complete metric space, with **uncountable** cardinality and lebesgue **measure zero**

Cantor dust (2D generalization): Cantor set crossed with itself

Cantor cube (3D):
Cantor set crossed with
itself three times

Historical Perspectives

Bertrand Russell (1872-1970)

- Philosopher, logician, mathematician, historian, social reformist, and pacifist
- Co-authored “**Principia Mathematica**” (1910)
- **Axiomatized mathematics** and set theory
- Co-founded **analytic philosophy**
- Originated **Russell’s Paradox**
- **Activist: humanitarianism**, pacifism, education, free trade, nuclear disarmament, birth control gender & racial equality, gay rights
- Profoundly **transformed math & philosophy**, mentored Wittgenstein, influenced Godel
- Laid **foundation** for computer science theory
- Won Nobel Prize in literature (1950)

The Problems of Philosophy

... Bertrand Russell, a Welsh atheist, wore many hats including philosopher, historical, logician, mathematician, and social reformer. In 1950 he won a Nobel Prize in literature for his humanitarianism and freedom of thought. In this book Russell attempts to give an easily accessible look at problems in philosophy.

Theorem pm54.43 4699

Description: Theorem *54.43 of [WhiteheadRussell] p. 360. "From this proposition it will follow, when arithmetical addition has been defined, that $1+1=2$." See http://en.wikipedia.org/wiki/Principia_Mathematica#Quotations. This theorem states that two sets of cardinality 1 are disjoint iff their union has cardinality 2.

Whitehead and Russell define 1 as the collection of all sets with cardinality 1 (i.e. all singletons; see [card1](#) 4965), so that their $A \in 1$ means, in our notation, $A \in \{x \mid (\text{card}^* x) = 1_o\}$ i.e. $(\text{card}^* A) = 1_o$ (by [elab](#) 1939) i.e. $A \approx 1_o$ (by [carden](#) 4963 and [cardm](#) 4954). We do not have several of their earlier lemmas available (which would otherwise be unused by our different approach to arithmetic), so our proof is longer. (It is also longer because we must show every detail.)

Theorem [pml10.643](#) 5057 shows the derivation of $1+1=2$ for cardinal numbers from this theorem.

Theorem pm110.643 ⁵⁰⁵⁷

Description: $1+1=2$ for cardinal number addition. Theorem *110.643 of *Principia Mathematica*, vol. II, p. 86, which adds the remark, "The above proposition is occasionally useful." Unlike us, Whitehead and Russell define cardinal addition on collections of all sets equinumerous to 1 and 2 (which for us are proper classes unless we restrict them as in [karden](#) 4856), but after applying definitions, our theorem is equivalent. See also the comment for [pm54.43](#) 4699. The comment for [cdavali](#) 5054 explains why we use \approx instead of $=$.

AUDIO MASTERWORKS LPA 1225

Russell's paradox was invented by Russell in 1901 to show that naïve set theory is self-contradictory:

Define: set of all sets that **do not contain themselves**

$$S = \{ T \mid T \notin T \}$$

Q: does S contain itself as an element?

$$S \notin S \Leftrightarrow S \in S \quad \text{contradiction!}$$

Similar **paradoxes**:

- “**A barber who shaves exactly those who do not shave themselves.**”
- “This sentence is false.”
- “I am lying.”
- “Is the answer to this question ‘no’?”
- “The smallest positive integer not describable in twenty words or less.”

Star Trek, 1967, "I, Mudd" episode
Captain James Kirk and Harry Mudd use a logical paradox to cause hostile android "Norman" to crash

AUTHOR KATHARINE GATES RECENTLY ATTEMPTED TO MAKE A CHART OF ALL SEXUAL FETISHES.

LITTLE DID SHE KNOW THAT RUSSELL AND WHITEHEAD HAD ALREADY FAILED AT THIS SAME TASK.

Problem: Give as many proofs as you can for the Pythagorean Theorem. i.e., $a^2 + b^2 = c^2$ holds for any right triangle with sides a & b and hypotenuse c .

Problem: Does the Pythagorean theorem generalize to arbitrary figures on the sides of a right triangle?

Pythagorean Theorem: $c^2 = a^2 + b^2$

Problem: compute 11111111^2 in your head.

Problem: What is the approximate value of:

$$(1+9^{-(4^{(7*6)})})^{(3^{(2^{85})})} \approx ?$$

Problem: Does every closed simple curve contain the vertices of an equilateral triangle?

$$\frac{1}{\pi} = \frac{2\sqrt{2}}{9801} \sum_{k=0}^{\infty} \frac{(4k)!(1103 + 26390k)}{(k!)^4 396^{4k}}$$

ABSTRACT

In 1976 quite by accident, I stumbled across a collection of about 100 sheets of mathematics in Ramanujan's handwriting; they were stored in a box in the Trinity College Library in Cambridge. I titled this collection "Ramanujan's Lost Notebook" to distinguish it from the famous notebooks that he had prepared earlier in his life. On and off for the past 32 years, I have studied these wild and confusing pages. Some of the weirder results have yielded entirely new lines of discovery. Sometimes, if you pay close attention, you can gain some possible insights about the searches that Ramanujan undertook and the questions he must have asked himself. Even if such speculations may be far from Ramanujan's actual thinking, they are nonetheless valuable exercises to undertake. Some of these flights of fancy will form the topics in this talk.

Ramanujan's Lost Notebook

Part I

“The
Hardy-Ramanujan
Number”

G. H. Hardy on Ramanujan:

“I remember once going to see him when he was ill at Putney. I had ridden in taxi cab number 1729 and remarked that the number seemed to me rather a dull one, and that I hoped it was not an unfavorable omen. ‘No,’ he replied, ‘it is a very interesting number; it is the smallest number expressible as the sum of two cubes in two different ways.’”

A Fermat “near-miss”:

$$1729 = 9^3 + 10^3 = 12^3 + 1^3$$

“My greatest contribution to mathematics was discovering Ramanujan.” - G. H. Hardy

“Ramanujan's theorems must be true, because, if they were not true, no one would have the imagination to invent them.”
- G. H. Hardy, upon first seeing Ramanujan's results

$$\frac{1}{\pi} = \frac{2\sqrt{2}}{9801} \sum_{k=0}^{\infty} \frac{(4k)!(1103 + 26390k)}{(k!)^4 396^{4k}}$$

$$\int_0^{\infty} \frac{1 + x^2/(b+1)^2}{1 + x^2/a^2} \times \frac{1 + x^2/(b+2)^2}{1 + x^2/(a+1)^2} \times \dots dx = \frac{\sqrt{\pi}}{2} \times \frac{\Gamma(a + \frac{1}{2})\Gamma(b+1)\Gamma(b-a + \frac{1}{2})}{\Gamma(a)\Gamma(b + \frac{1}{2})\Gamma(b-a+1)}$$

$$\frac{1}{1 + \frac{e^{-2\pi}}{1 + \frac{e^{-4\pi}}{1 + \dots}}} = \left(\sqrt{\frac{5 + \sqrt{5}}{2}} - \frac{\sqrt{5} + 1}{2} \right) e^{2\pi/5} = e^{2\pi/5} \left(\sqrt{\varphi\sqrt{5}} - \varphi \right) = 0.9981$$

$$1 + 9 \left(\frac{1}{4}\right)^4 + 17 \left(\frac{1 \times 5}{4 \times 8}\right)^4 + 25 \left(\frac{1 \times 5 \times 9}{4 \times 8 \times 12}\right)^4 + \dots = \frac{2^{\frac{3}{2}}}{\pi^{\frac{1}{2}} \Gamma^2\left(\frac{3}{4}\right)}$$

$$\left[1 + 2 \sum_{n=1}^{\infty} \frac{\cos(n\theta)}{\cosh(n\pi)} \right]^{-2} + \left[1 + 2 \sum_{n=1}^{\infty} \frac{\cosh(n\theta)}{\cosh(n\pi)} \right]^{-2} = \frac{2\Gamma^4\left(\frac{3}{4}\right)}{\pi}$$

$$1 - 5 \left(\frac{1}{2}\right)^3 + 9 \left(\frac{1 \times 3}{2 \times 4}\right)^3 - 13 \left(\frac{1 \times 3 \times 5}{2 \times 4 \times 6}\right)^3 + \dots = \frac{2}{\pi}$$

“Amrita Ramanujan”

Historical Perspectives

Frank Ramsey (1903-1930)

- Contributed to mathematics, decision theory, game theory, logic, philosophy, economics
- Pioneered Ramsey theory
- Was Wittgenstein's Ph.D. advisor
- Influenced Church, von Neumann, Keynes
- Died at age 26

Pigeon-Hole Principle

- J. Dirichlet (1834)
- “Drawer principle”
- “Shelf Principle”
- “Box principle”

Theorem (pigeon-hole): There is no injective (1-to-1) function from a finite set (domain) to a smaller finite set (range).

Generalization:

N objects placed in M containers; then:

- at least 1 container must hold $\geq \left\lceil \frac{N}{M} \right\rceil$
- at least 1 container must hold $\leq \left\lfloor \frac{N}{M} \right\rfloor$

Problem: Show that any group of **six** people contains either **3** mutual friends or **3** mutual strangers.

Q: Is this true for **N=5**?

No mono-chromatic triangles

Brute force approach?

78 possible friends-strangers
graphs with **6** nodes

A more elegant approach is needed!

Problem: Show that any group of **six** people contains either **3** mutual friends or **3** mutual strangers.

Pigeon-hole principle!

6 is said to be the “Ramsey number” $R(3,3)$.

Theorem: any group of **18** people contains either **4** mutual friends or **4** mutual strangers. $R(4,4)=18$

Ramsey Theory

- $R(3,3)=6$ is the tip of a deep mathematical theory.

Theorem [Ramsey]: For any pair of positive integers b and r , there exists a least positive integer $R(b,r)$ such that any complete graph over $R(b,r)$ vertices, where each edge is colored either blue or red, contains a monochromatic clique of size b or r .

- Ramsey theory seeks “order” among “chaos”:
i.e., even “random” graphs / configurations still contain regular and predictable sub-structures.
- Pigeon-hole principle is a special case!

Other known Ramsey numbers (and bounds):

r,s	1	2	3	4	5	6	7	8	9	10
1	1	1	1	1	1	1	1	1	1	1
2	1	2	3	4	5	6	7	8	9	10
3	1	3	6 = $R(3,3)$	9	14	18	23	28	36	40–43
4	1	4	9	18	25	35–41	49–61	56–84	73–115	92–149
5	1	5	14	25	43–49	58–87	80–143	101–216	125–316	143–442
6	1	6	18	35–41	58–87	102–165	113–298	127–495	169–780	179–1171
7	1	7	23	49–61	80–143	113–298	205–540	216–1031	233–1713	289–2826
8	1	8	28	56–84	101–216	127–495	216–1031	282–1870	317–3583	≤ 6090
9	1	9	36	73–115	125–316	169–780	233–1713	317–3583	565–6588	580–12677
10	1	10	40–43	92–149	143–442	179–1171	289–2826	≤ 6090	580–12677	798–23556

“Imagine an alien force, vastly more powerful than us, landing on Earth and demanding the value of $R(5,5)$ or they will destroy our planet. In that case, we should marshal all our computers and all our mathematicians and attempt to find the value. But suppose, instead, that they ask for $R(6,6)$. In that case, we should attempt to destroy the aliens.” – Paul Erdős (1913-1996)

Generalizations of Ramsey numbers

- **Multi-colors**: only known non-trivial exact value is $R(3,3,3)=17$
E.g.: 16-node graph containing no mono-chromatic triangles:

Extra credit:
prove that
 $R(3,3,3)=17$

- **Hypergraphs** (where “edges” can be vertex subsets of size > 2)
- **Infinite graphs** (which imply the finite cases as a corollary)

“*Complete disorder is impossible.*”

– T. S. Motzkin (1908-1970)

Historical Perspectives

David Hilbert (1862-1943)

- One of the most influential mathematicians
- Developed **invariant theory**, **Hilbert spaces**
- **Axiomatized geometry**, “Hilbert’s axioms”
- Co-founded **proof theory**, **mathematical logic**, **meta-mathematics**, & formalist school
- Created famous list of **23 open problems** that greatly impacted mathematics research
- Defended Cantor’s **transfinite numbers**
- Contributed to **relativity theory** & physics
- Hilbert’s students included Courant, Hecke, Lasker, Weyl, Ackermann, and Zermelo
- **Influenced Russell, Gödel, Church, & Turing**
John von Neumann was Hilbert’s assistant!

INSTITUTE

Introduction from Hilbert's Lecture

“Who of us would not be glad to lift the veil behind which the future lies hidden; to cast a glance at the next advances of our science and at the secrets of its development during future centuries? What particular goals will there be toward which the leading mathematical spirits of coming generations will strive? What new methods and new facts in the wide and rich field of mathematical thought will the new centuries disclose?”

History teaches the continuity of the development of science. We know that every age has its own problems, which the following age either solves or casts aside as profitless and replaces by new ones. If we would obtain an idea of the probable development of mathematical knowledge in the immediate future, we must let the unsettled questions pass before our minds and look over the problems which the science of today sets and whose solution we expect from the future. To such a review of problems the present day, lying at the meeting of the centuries, seems to me well adapted. For the close of a great epoch not only invites us to look back into the past but also directs our thoughts to the unknown future.

The deep significance of certain problems for the advance of mathematical science in general and the important role which they play in the work of the individual investigator are not to be denied. As long as a branch of science offers an abundance of problems, so long is it alive; a lack of problems foreshadows extinction or the cessation of independent development. Just as every human undertaking pursues certain objects, so also mathematical research requires its problems. It is by the solution of problems that the investigator tests the temper of his steel; he finds new methods and new outlooks, and gains a wider and freer horizon.

It is difficult and often impossible to judge the value of a problem correctly in advance; for the final award depends upon the gain which science obtains from the problem. Nevertheless we can ask whether there are general criteria which mark a good mathematical problem. An old French mathematician said: "A mathematical theory is not to be considered complete until you have made it so clear that you can explain it to the first man whom you meet on the street." This clearness and ease of comprehension, here insisted on for a mathematical theory, I should still more demand for a mathematical problem if it is to be perfect; for what is clear and easily comprehended attracts, the complicated repels us.

Moreover a mathematical problem should be difficult in order to entice us, yet not completely inaccessible, lest it mock at our efforts. It should be to us a guide post on the mazy paths to hidden truths, and ultimately a reminder of our pleasure in the successful solution.”

Occam's
Razor!

Hilbert's Problems

Problem 1: The **continuum hypothesis** (conjectured by Georg Cantor: there is no set whose cardinality is strictly between those of the integers and the reals)

Status: The continuum hypothesis was proven by Gödel (1939) and Cohen (1963) to be **independent** of (i.e., impossible to prove or disprove) Zermelo–Frankel set theory. Related open questions remain (e.g., regarding the generalized continuum hypothesis), and there is still much active research in this area.

Problem 2: Prove the axioms of arithmetic are **consistent**.

Status: Gödel (1931) proved that the consistency of Peano arithmetic can not be proven within Peano arithmetic itself. Gödel also proved that **every consistent formal axiomatic system is incomplete**. Gentzen (1936) proved the consistency Peano arithmetic within a different system (that is weaker than set theory).

Hilbert's Problems

Problem 3: Given any **two polyhedra** of equal volume, is it always possible to **cut** the first into finitely many polyhedral pieces which can be **reassembled** to yield the second?

Status: Proved via counter-example to be **impossible** by Hilbert's student Dehn (1901). The Wallace-Bolyai–Gerwien theorem (1807): in 2D this is always possible for polygons of equal areas.

Problem 4: Construct all metrics where lines are geodesics.

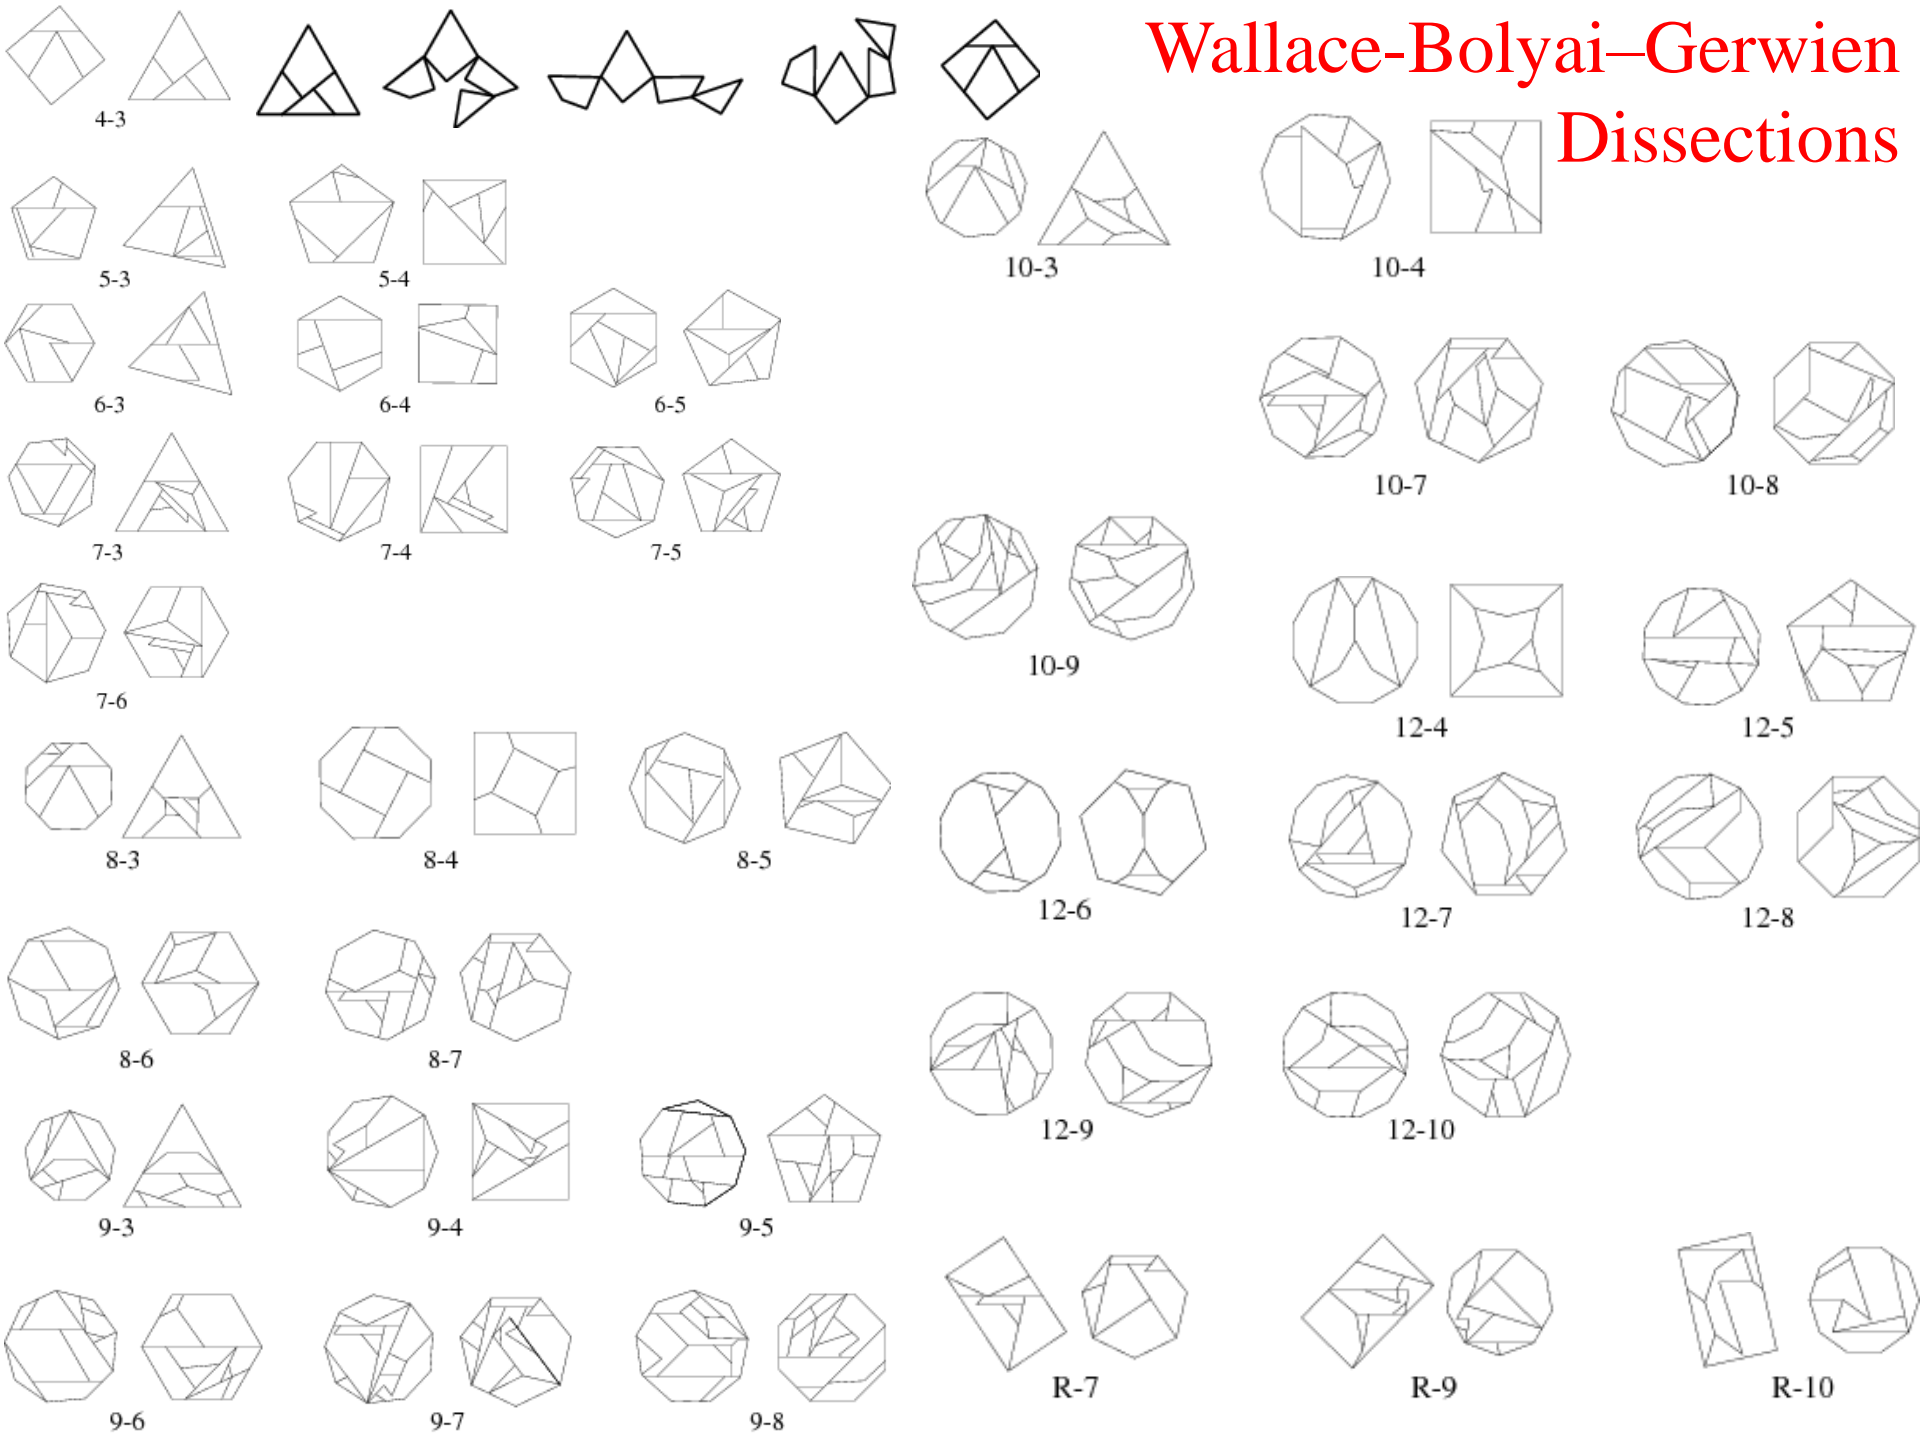

Status: Too vague for a definite answer.

Problem 5: Are continuous groups automatically differential groups?

Status: Resolved in the negative by von Neumann (1929), Pontryagin (1934), Gleason-Montgomery-Zippin (1950's), and Yamabe (1953).

Wallace-Bolyai–Gerwien Dissections

Wallace-Bolyai–Gerwien Dissections

Hilbert's Problems

Problem 6: Axiomatize all of physics.

Status: Since Hilbert stated this problem in 1900, **relativity** theory was developed by Einstein (1905 and 1915), as was **quantum mechanics** by Dirac (1920's), followed by other more modern approaches, e.g. **quantum field theory**, the **standard model**, **quantum gravity**, and **string theory**. Hilbert himself made significant contributions to relativity and physics, but his original problem/goal of axiomatizing all of physics remains mostly open.

Problem 7: Is a^b transcendental, for algebraic $a \neq 0, 1$ and irrational algebraic b ?

Status: Shown to be **true** by Gelfond and Schneider (1934), even for complex a and b . This proves that, e.g.,

$$e^\pi \quad i^i \quad 2^{\sqrt{2}} \quad \sqrt{2}^{\sqrt{2}}$$

are all transcendental. But many similar problems remain **open**, such as the transcendence (or even the irrationality) of π^e , 2^e , or even $\pi + e$ and π / e .

Hilbert's Problems

Problem 8: The **Riemann hypothesis** (the real part of any non-trivial zero of the Riemann zeta function is $\frac{1}{2}$) and **Goldbach's conjecture** (every even number > 2 can be written as the sum of two primes).

Status: Both the Riemann hypothesis (1859) and Goldbach's conjecture (1742) **remain open** to this day. The Riemann hypothesis has many far-reaching implications in mathematics, logic, and computer science. It was **numerically verified for the first ten trillion zeroes**, and appears on the Millennium Prize list (\$1M bounty) as well as the ARPA Mathematical Challenges List. The **Goldbach conjecture was verified for the first 10^{18} values**.

Problem 9: Find most general law of the **reciprocity** theorem in any algebraic number field.

Status: Partially **solved** by Artin (1924), Takagi & Hassel (1930) and Shafarevich (1948); still some open issues.

$$\zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s}$$

Evidence for Goldbach's conjecture: the number of distinct ways to write an even number as the sum of two primes (computational data for $4 < n < 1,000,000$):

Theorem (Jingrun, 1973): Every sufficiently large even number can be written as either the sum of two primes, or the sum of a prime and a product of two primes.

Theorem (Ramaré, 1995): Every even number >2 is the **sum of at most six primes**.

Millennium Problems

In order to celebrate mathematics in the new millennium, The Clay Mathematics Institute of Cambridge, Massachusetts (CMI) has named seven *Prize Problems*. The Scientific Advisory Board of CMI selected these problems, focusing on important classic questions that have resisted solution over the years. The Board of Directors of CMI designated a **\$7 million prize fund for the solution to these problems, with \$1 million allocated to each**. During the Millennium Meeting held on May 24, 2000 at the Collège de France, Timothy Gowers presented a lecture entitled *The Importance of Mathematics*, aimed for the general public, while John Tate and Michael Atiyah spoke on the problems. The CMI invited specialists to formulate each problem.

One hundred years earlier, on August 8, 1900, David Hilbert delivered his famous lecture about open mathematical problems at the second International Congress of Mathematicians in Paris. This influenced our decision to announce the millennium problems as the central theme of a Paris meeting.

The rules for the award of the prize have the endorsement of the CMI Scientific Advisory Board and the approval of the Directors. The members of these boards have the responsibility to preserve the nature, the integrity, and the spirit of this prize.

Hilbert's Problems

Problem 10: Find an **algorithm** that determines whether a given Diophantine (i.e., multi-variable **polynomial**) equation has any **integer solutions**.

Ex: $x^2+y^2=z^2$ has many integer solutions

(Pythagorean theorem, e.g., $x=3$, $y=4$, $z=5$)

$x^9+y^9=z^9$ has no integer solutions (corollary of Fermat's Last Theorem, conjectured in 1637, proved in 1995 by Andrew Wiles)

Many attempts at solution & partial results: **Emil Post** (1944), **Martin Davis** (1949), **Julia Robinson** (1950), **Hilary Putnam** (1959)

Martin Davis

Hilbert's Tenth Problem

Solving even simple Diophantine equations is hard:

Q: \exists an integer solution for $x^3 + y^3 + z^3 = 29$?

A: Yes: $x=3, y=1, z=1$

Q: \exists an integer solution for $x^3 + y^3 + z^3 = 30$?

A: Yes: $x = 2220422932, y = -2218888517, z = -283059965$

Q: \exists an integer solution for $x^3 + y^3 + z^3 = 33$?

A: still unknown!

Q: Is $\{x^3 + y^3 + z^3 \mid x, y, z \in \mathbb{Z}\} = \mathbb{Z}$?

A: still unknown!

Q: Is $\{x^3 + y^3 + z^3 \mid x, y, z \in \mathbb{Z}\}$ Turing-decidable?

A: still unknown!

Theorem [Lagrange]: $\{w^2 + x^2 + y^2 + z^2 \mid w, x, y, z \in \mathbb{Z}\} = \mathbb{Z}$

$(2220422932)^3 + (-2218888517)^3 + (-283059965)^3$

 [Examples](#)  [Random](#)

Input:

$$2\,220\,422\,932^3 + (-2\,218\,888\,517)^3 + (-283\,059\,965)^3$$

Result:

Pigeon-Hole Principle

- J. Dirichlet (1834)
- “Drawer principle”
- “Shelf Principle”
- “Box principle”

Theorem (pigeon-hole): There is no injective (1-to-1) function from a finite set (domain) to a smaller finite set (range).

Generalization:

N objects placed in M containers; then:

- at least 1 container must hold $\geq \left\lceil \frac{N}{M} \right\rceil$
- at least 1 container must hold $\leq \left\lfloor \frac{N}{M} \right\rfloor$

Hilbert's Tenth Problem

Theorem [Matiyasevich, 1970]: Every Turing-enumerable set is Diophantine (i.e., the solutions of some polynomial)

Ex: the set of primes coincides exactly with the positive values of this 26-variable polynomial:

$$\begin{aligned} & (k + 2)(1 - [wz + h + j - q]^2 - [(gk + 2g + k + 1)(h + j) + h - z]^2 \\ & - [16(k + 1)^3(k + 2)(n + 1)^2 + 1 - f^2]^2 - [2n + p + q + z - e]^2 \\ & - [e^3(e + 2)(a + 1)^2 + 1 - o^2]^2 - [(a^2 - 1)y^2 + 1 - x^2]^2 \\ & - [16r^2y^4(a^2 - 1) + 1 - u^2]^2 - [n + l + v - y]^2 - [(a^2 - 1)l^2 + 1 - m^2]^2 \\ & - [ai + k + 1 - l - i]^2 - [((a + u^2(u^2 - a))^2 - 1)(n + 4dy)^2 + 1 \\ & - (x + cu)^2]^2 - [p + l(a - n - 1) + b(2an + 2a - n^2 - 2n - 2) - m]^2 \\ & - [q + y(a - p - 1) + s(2ap + 2a - p^2 - 2p - 2) - x]^2 \\ & - [z + pl(a - p) + t(2ap - p^2 - 1) - pm]^2 \end{aligned}$$

as a, b, c, ..., z range over the nonnegative integers!

Hilbert's Tenth Problem

Corollary [Matiyasevich, 1970]: There is a fixed “universal” polynomial P such that for any Turing-enumerable set S there exists an integer n_0 such that:

$$S = \{w \mid \exists x_1, x_2, \dots, x_k \ni P(n_0, w, x_1, x_2, \dots, x_k) = 0\}$$

i.e., there is a fixed polynomial that can “output” any computable set, depending on one parameter.

This is an analogue of a universal Turing machine!

Hilbert's Tenth Problem

Q: What is the minimum Diophantine **degree** and **dimension** (i.e., number of variables) of a given Turing-enumerable set?

Theorem [Skolem]: **degree 4 suffices.**

Theorem [Matiyasevich]: **dimension 9 suffices.**

But there is a dramatic **tradeoff** between the **degree** and the **number of variables.**

$$\begin{aligned} & (k+2)(1 - [wz + h + j - q]^2 - [(gk + 2g + k + 1)(h + j) + h - z]^2 \\ & - [16(k+1)^3(k+2)(n+1)^2 + 1 - f^2]^2 - [2n + p + q + z - e]^2 \\ & - [e^3(e+2)(a+1)^2 + 1 - o^2]^2 - [(a^2 - 1)y^2 + 1 - x^2]^2 \\ & - [16r^2y^4(a^2 - 1) + 1 - u^2]^2 - [n + l + v - y]^2 - [(a^2 - 1)l^2 + 1 - m^2]^2 \\ & - [ai + k + 1 - l - i]^2 - [((a + u^2(u^2 - a))^2 - 1)(n + 4dy)^2 + 1 \\ & - (x + cu)^2]^2 - [p + l(a - n - 1) + b(2an + 2a - n^2 - 2n - 2) - m]^2 \\ & - [q + y(a - p - 1) + s(2ap + 2a - p^2 - 2p - 2) - x]^2 \\ & - [z + pl(a - p) + t(2ap - p^2 - 1) - pm]^2 \end{aligned}$$

This is analogous to finding **small universal TMs** (where there is a tradeoff between the alphabet size and the number of states).

function appear. Next these are eliminated so that we obtain a system of purely polynomial equations.

THEOREM 3. *In order that $x \in W_{(z,u,y)}$, it is necessary and sufficient that the following system of equations has a solution in positive integers.*

$$\begin{aligned}
 elg^2 + \alpha &= (b - xy)q^2, \quad q = b^{560}, \quad \lambda + q^4 = 1 + \lambda b^5, \\
 \theta + 2z &= b^5, \quad l = u + t\theta, \quad e = y + m\theta, \quad n = q^{16}, \\
 r &= [g + eq^3 + lq^5 + (2(e - z\lambda)(1 + xb^5 + g)^4 + \lambda b^5 + \lambda b^5 q^4)q^4] [n^2 - n] \\
 &\quad + [q^3 - bl + l + \theta\lambda q^3 + (b^5 - 2)q^5] [n^2 - 1], \\
 p &= 2ws^2r^2n^2, \quad p^2k^2 - k^2 + 1 = \tau^2, \quad 4(c - ksn^2)^2 + \eta = k^2, \\
 k &= r + 1 + hp - h, \quad a = (wn^2 + 1)rsn^2, \\
 c &= 2r + 1 + \varphi, \quad d = bw + ca - 2c + 4\alpha\gamma - 5\gamma, \quad d^2 = (a^2 - 1)c^2 + 1, \\
 f^2 &= (a^2 - 1)^2c^4 + 1, \quad (d + of)^2 = ((a + f^2(d^2 - a))^2 - 1)(2r + 1 + jc)^2 + 1.
 \end{aligned}$$

The equations of Theorem 3 have twenty eight unknowns, $a, b, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, w, \alpha, \gamma, \eta, \theta, \lambda, \tau, \varphi$. The degree is 5^{60} , however the equation $q = b^{560}$ can be replaced by certain others of low degree. In fact, by introducing some 30 additional unknowns and new equations one can reduce the degree of the system to 2. Then, by transposing terms to one side and summing squares one can construct a universal diophantine equation in 58 unknowns and degree 4.

Alternatively one may try instead to reduce the total number of unknowns, v . In [6] Julia Robinson and Ju. Matijasevič showed that v can be reduced universally to 13. More recently Matijasevič [5] has improved this to $v = 9$. The corresponding value of the degree, δ is however very large. The following table gives various simultaneous possibilities for δ and v , sufficient for a universal equation.

THEOREM 4. *The following pairs are universal.*

$v = 58,$	$\delta = 4$	$v = 21,$	$\delta = 96$
$v = 38,$	$\delta = 8$	$v = 19,$	$\delta = 2668$
$v = 32,$	$\delta = 12$	$v = 14,$	$\delta = 2.0 \times 10^5$
$v = 29,$	$\delta = 16$	$v = 13,$	$\delta = 6.6 \times 10^{43}$
$v = 28,$	$\delta = 20$	$v = 12,$	$\delta = 1.3 \times 10^{44}$
$v = 26,$	$\delta = 24$	$v = 11,$	$\delta = 4.6 \times 10^{44}$
$v = 25,$	$\delta = 28$	$v = 10,$	$\delta = 8.6 \times 10^{44}$
$v = 24,$	$\delta = 36$	$v = 9,$	$\delta = 1.6 \times 10^{45}$

From "Undecidable Diophantine Equations" by James P. Jones, Bulletin of the American Mathematical Society, vol 2, No 3, 1980, pp. 859-862.

Tradeoff between degree and the number of variables in universal polynomials:

Examples:

- 58 variables & degree 4 suffice
- 28 variables & degree 20 suffice
- 19 variables & degree 2668 suffice
- 14 variables & degree $\sim 10^5$ suffice
- 13 variables & degree $\sim 10^{43}$ suffice
- 9 variables & degree $\sim 10^{45}$ suffice

Corollary: 100 additions and/or multiplications suffice to "prove" any provable proposition.

Catch: using very large integers!

Hilbert's Problems

Problem 11: Solving **quadratic forms** with algebraic numerical coefficients.

Status: Partially solved by Hasse (1923).

Problem 12: Extend the **Kronecker–Weber theorem** on abelian extensions of the rational numbers to any base number field.

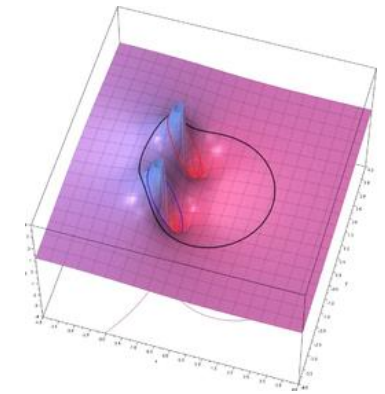

Status: Still unsolved.

Problem 13: Solve all **7-th degree equations** using functions of two parameters.

Status: Partially solved by Kolmogorov (1956), Arnold (1957), and Shimura (1976).

Problem 14: Proof of the **finiteness** of certain complete systems of functions.

Status: Counter-examples found by Nagata (1959).

Hilbert's Problems

Problem 15: Find a rigorous foundation for Schubert's enumerative calculus.

Status: Partially resolved.

Problem 16: Topology of algebraic curves and surfaces.

Status: Open-ended: some results, but unresolved.

Problem 17: Expression of definite rational function as quotient of sums of squares

Status: Resolved in the affirmative by Artin (1927) and Delzel (1984).

Hilbert's Problems

Problem 18: Is there a non-regular, **space-filling polyhedron**? What is the densest sphere packing?

Status: **Anisohedral tilings** were found in 3D by Reinhardt (1928), and for 2D by Heesch (1935).

Sphere packing in 3D (Kepler's problem, 1611) was solved by Toth (1953) and Hale (1998). Regular sphere packing in 24 dimensions was solved by Cohn and Kumar (2004), where the "**kissing number**" is 196,560.

Many related open problems remain, including non-regular, non-uniform, and **ellipsoid packings**.

Aperiodic Tilings

Goal: **tile** the entire **plane** without overlaps, non-periodically

- **Non-periodic** tiling is **not equal** to a **translation** of itself
- **Aperiodic** tile set **admits only non-periodic tilings**

“**Kites and Darts**” **2-tile** aperiodic set, Roger Penrose, 1974

Open question:

\exists a **single-tile 2D**
aperiodic tiling?

Aperiodic Tilings

Penrose tilings in architecture and design:

Aperiodic Tilings

“**Pinwheel tiling**”, John Conway and Charles Radin, 1992

- Tiles occur in **infinitely many orientations**, with uniform distribution!
- Despite **irrational edge lengths** and **incommensurable angles**, all vertices of tiles have **rational coordinates**!

Aperiodic Tilings

“Pinwheel tiling”, John Conway and Charles Radin, 1992

SCIENCE

Bathroom tiling to drive you mad

Ian Stewart

AN AMERICAN mathematician has come up with what is probably the strangest way ever of covering a floor or wall with tiles. The set of tiles which has been devised by Charles Radin of the University of Texas at Austin can only be assembled in a highly complex way (*Annals of Mathematics*, vol 109, p 661).

The usual way of assembling tiles is in a periodic pattern, one that starts with a basic unit, which is repeated at regularly spaced intervals. However, more complex patterns of tiling are perfectly possible and the subject of aperiodic tilings was created by the philosopher Hao Wang in 1961. Wang was studying the existence or otherwise of certain “decision procedures” in mathematical logic—ways of working out in advance whether certain problems have solutions—when he came to the surprising conclusion that the problem could be reformulated in terms of tiles.

Choose a finite collection of shapes and call them prototiles. A tiling is then a way to assemble perfect copies of those prototiles so that they cover the entire infinite plane without any gaps or overlaps. Wang discovered that he could design prototiles that corresponded to various logical statements, in such a way that the rules for fitting prototiles together corresponded exactly to the rules of logical deduction. So, in effect, a tiling pattern corresponded to a logical proof. This new viewpoint led Wang to ask whether there existed a set of prototiles that could tile the plane, but could not tile it periodically.

Tiling a plane aperiodically turns out to be easy. It can be done with a single domino-shaped prototile. First, however, it is necessary to tile the plane with squares. Then each square is divided into two dominos by splitting it in half in either the vertical or horizontal direction. If the pattern of verticals and horizontals is aperiodic, so too is the tiling; the easiest method is to vary the directions randomly. However, dominos can also tile the plane periodically—for example, by making all splits point the same way.

Wang wanted something much more subtle: a set of prototiles that produced only aperiodic tilings. Such a set of tiles was found in 1966 by his student Robert Berger. The best known of such sets are the Penrose tilings, introduced by Roger Penrose of the University of Oxford in 1977; these produce tilings with fivefold “almost” symmetries.

Radin notes that: “All published examples . . . have the feature that in every tiling each prototile only appears in finitely many orientations.” For instance, dominos can be laid down horizontally or vertically but not oriented at any other angle; and Penrose tiles rotate only through multiples of an angle of 36° . This means that if the set of prototiles is expanded so that it includes a copy of each prototile in each orientation, then the new prototiles can tile the whole plane without being rotated. Only translations of these “oriented prototiles” are then needed.

Radin’s new discovery is a set of

World’s most complex tiling? Surround a triangular “half-domino” by four more. Then simply repeat . . .

prototiles that are forced to appear in an infinite number of orientations. Because periodic tilings involve only a finite number of directions—the ones in the basic repeating unit—Radin’s tilings are necessarily aperiodic.

His starting point is an idea thought up by John Horton Conway of Princeton University in New Jersey. Begin with a “half-domino” prototile, a right triangle of sides 1 and 2 units (whose hypotenuse is 5 units). This can be surrounded by four copies of itself in order to create a triangle of the same shape, but larger and rotated through an angle of 36° (see Figure). The process can be thought of as defining a “level-1”

tiling of part of the plane with five triangular tiles. The construction can now be repeated, surrounding the level-1 set of five tiles with four copies of those sets to make an even larger and further rotated triangle that is composed of 25 of the original prototiles: this is known as the level-2 tiling.

Continuing this “expansion” process indefinitely from each level to the next leads to a strange, random-looking tiling of the infinite plane by half-dominos (see Figure), called the Conway tiling. Because the angle of rotation at each stage does not exactly divide into an integer number of full turns, the half-domino appears in an infinite number of different orientations throughout the plane.

However, this particular prototile can also tile the plane periodically. This can be done if two half-dominos are stuck together to make a domino and the plane is tiled periodically with those. To eliminate these periodic possibilities, Radin modifies the construction so that certain features of the Conway tiling, in particular its hierarchical structure into levels, cannot be avoided.

The essential idea is an old one: the edges of prototiles can be “labelled” with marks or symbols, with the extra rule that adjacent tiles must have matching labels along their common edges. This produces a larger set of labelled prototiles with more restrictive tiling rules. The point is that the labels can be realised by making notches in the edges of one tile and adding protruding lugs to match them in the adjacent tile. By using a different shaped notch/lug pair for each symbol used as a label, we can convert labelled prototiles into ordinary ones of more complicated shapes.

It is, of course, easier to think about simple shapes that have labelled edges, and this is the way in which Radin proceeds. His prototiles are labelled half-dominos, and he invents a complicated range of different labels whose matching rules cleverly force the appearance of the same structure as the Conway tiling.

It is astonishing that such a simple shape as half a domino can have such curious implications, and it shows that even in today’s complex world mathematics can still advance by looking at a simple idea in a new way. □

Undecidability of Tiling Problem

Q [Wang, 1961]: Is there an **algorithm** for determining whether a given set of tiles can tile the entire plane? (Tiles can not be rotated)

Wang gave a decision algorithm for periodic tilings (and falsely assumed that non-periodic tilings do not exist).

Theorem [Berger, 1966]: Tiling is **undecidable**.

Proof idea: A tiling can “**simulate**” an arbitrary Turing computation.

Berger discovered a set of 20,426 Wang tiles that can tile the plane only **aperiodically**, and conjectured that smaller sets exist.

Theorem [Culik, 1996]: The following 13 tiles is an **aperiodic** tiling set.

Wang Cubes for Fast Geometry Placement & Video Synthesis

Peter G. Sibley[†], Philip Montgomery, G. Elisabeta Marai
Brown University

1. Abstract

We present an extension of Cohen's Wang Tiles to three dimensions: Wang Cubes. Cubes are filled with video or Poisson distributed points to perform realtime video synthesis or geometry placement. Video synthesis from a sample is useful for generating dynamic backgrounds for games or special effects but costly in terms of storage and runtime. Randomly positioning non-overlapping 3D geometry is useful for simulations and games but also costly. We propose Wang Cubes where we only store 32 cubes and generate, at runtime, large amounts of synthesized video, or Poisson distributed geometry

2. Methods

Cohen et al. introduced a fast and simple stochastic algorithm to generate an aperiodic tiling of the plane with as few as eight Wang Tiles (oriented squares with color associated edges). Cohen et al. used these tilings for texture synthesis and 2D geometry placement.

Figure 1: A valid tiling of Wang Tiles, from Cohen et al.

We extend these applications to the 3D case, where cubes with colored faces replace tiles. 32 cubes are sufficient to tile space. The extended tiling algorithm iterates through the space, placing a cube at each point (Figure 2). The 32 cubes contain either Poisson ball distributed points or video data and are tiled at runtime to generate large stretches of 3D geometry or video sequences.

Figure 2: Aligning face colors of Wang Cubes

To place geometry data, we use dart-throwing to fill each cube with Poisson distributed points. Several iterations of Lloyd's relaxation are applied to prevent points near boundaries from violating the minimum distance constraint in tiling.

Figure 3: Assembling six octahedra of video to form one cube.

To fill the cubes with video data, we cut six octahedra from the video stream and stitch them together through the graph cut method of Kwatra et al. Then, the result is trimmed into a cube (Figure 3). Each original octahedron is associated with a face color. A xy plane in this cube corresponds to a frame of video and the z axis corresponds to time (Figure 4).

Figure 4: Several slices of one cube showing the seam of the bottom tetrahedron.

3. Geometry Results

Figure 6: Single Asteroid.

Figure 7: Saturn Asteroid belt, 5959 asteroid instances placed using tiling of 3972 cubes each with 15 Poisson distributed points. Note, this took only seconds to generate. Filling the same region with dart throwing is simply infeasible.

As a geometry placement application, we modeled the asteroid belt of Saturn with 5958 asteroids (Figure 6) constructed from 3972 tiled cubes with 15 points in each cube. The asteroids are placed according to a Poisson distribution in this large area (Figures 7 and 8). It only took 15 minutes to precompute the cubes, and under 20 seconds to tile them. Note that filling the same region with dart throwing is simply infeasible. Teapot geometry and sheep billboard distributions are shown in Figures 9 and 11. These tests were performed on an AMD Athlon XP 1800 with 512MB of memory.

Figure 8: An overhead of the Saturn Asteroid belt.

Figure 9: An infinite teapot field. Note the teapot instances are neither colliding nor have a regular position pattern.

4. Video Results

We constructed a cube set (64*64*64 voxels per cube) from a video of simulated shallow pool caustics. Three vertical slices through two cubes tiled horizontally are shown in Figure 10. Note how the vertical seam in the middle of each frame is invisible. An infinite caustics pool (both in space and time) could be generated in this manner.

Figure 10: Vertical slices from two tiled Wang cubes. Note that the vertical middle seam of each frame is invisible

In order to keep our computation feasible, we constrained the cuts to lie near the intersecting triangles of the octahedra. We have noticed temporal artifacts in the videos, a growing and shrinking square-discontinuity. We believe these are caused by constrained cuts and small cube sizes.

5. Discussion and Future Work

For video synthesis, we restricted the space searched for a min-cut surface, sacrificing quality of the cut for faster execution. Also, because of computational constraints we could only use quite small cube sizes (64*64*64). Implementing known randomized max-flow algorithms to approximate the cut could yield much lower preprocessing, which would allow for less constrained cuts and eliminate temporal artifacts. Incorporating newer texture synthesis techniques could produce better quality cubes.

Figure 11: A sheep belt instead of an asteroid belt.

Hilbert's Problems

Problem 19: Are solutions of Lagrangians always analytic?

Status: Resolved in the affirmative by Bernstein (1904).

Problem 20: Do all variational problems with certain boundary conditions have solutions?

Status: Resolved in the affirmative.

Problem 21: Proof of the existence of linear differential equations having a prescribed monodromic group

Status: Resolved by Plemelj (1908), Schlesinger (1964), Dekkers (1978), and Bolibrukh (1989).

Problem 22: Uniformization of analytic relations by means of automorphic functions

Status: Resolved.

Problem 23: Further development in calculus of variations

Status: Unresolved.

DARPA invests in math

STORY HIGHLIGHTS

- Mathematicians being offered new challenges designed to "revolutionize" math
- One challenge is solving the Reimann Hypothesis, unsolved since before 1900
- New math could propel other sciences, including biology, computing, physics

[Next Article in Technology »](#)

DARPA Mathematical Challenges

It's rare for mathematicians to be publicly challenged with solving the problems of the universe. In 1900, David Hilbert issued 23 iconic problems; in 2000, the Clay Mathematics Institute offered the Millennium Prize Problems; and DARPA's were

The latest set of challenges

In 2007, the Defense Advanced Research Projects Agency (DARPA) issued 23 mathematical challenges in order to "dramatically [revolutionize] mathematics and thereby [strengthen] the scientific and technological capabilities of [the Department of Defense.]" CNN spoke with John Etnyre, a professor of mathematics at the Georgia Institute of Technology, to get an inside look at some of these challenges and why the mathematical community is interested in them.

Etnyre, who specializes in low-dimensional topology and geometry, says he finds the fluids and 4D problems on DARPA's list to be especially interesting, and he is considering tackling those challenges himself.

DARPA's Mathematical Challenges

“**DARPA-hard**” problems!

http://www.gogeometry.com/mindmap/darpa_mathematical_challenges_elearning.html
<http://www.mathisfunforum.com/viewtopic.php?id=10753>

DARPA's Mathematical Challenges

- 1: **The Mathematics of the Brain**: Develop a mathematical theory to build a functional model of the brain that is mathematically consistent and predictive rather than merely biologically inspired.
- 2: **The Dynamics of Networks**: Develop the **high-dimensional mathematics** needed to accurately model and predict behavior in large-scale distributed networks that evolve over time occurring in communication, biology and the social sciences.
- 3: **Capture and Harness Stochasticity in Nature**: Address Mumford's call for new mathematics for the 21st century. Develop methods that capture persistence in stochastic environments.
- 4: **21st Century Fluids**: Classical fluid dynamics and the Navier-Stokes Equation were extraordinarily successful in obtaining quantitative understanding of shock waves, turbulence and solitons, but new methods are needed to tackle complex fluids such as foams, suspensions, gels and liquid crystals.
- 5: **Biological Quantum Field Theory**: Quantum and statistical methods have had great success modeling virus evolution. Can such techniques be used to model more complex systems such as bacteria? Can these techniques be used to control pathogen evolution?
- 6: **Computational Duality**: Duality in mathematics has been a profound tool for theoretical understanding. Can it be extended to develop principled computational techniques where duality and geometry are the basis for novel algorithms?

DARPA's Mathematical Challenges

- 7: **Occam's Razor** in Many Dimensions: As data collection increases can we “do more with less” by finding lower bounds for sensing complexity in systems? This is related to questions about entropy maximization algorithms.
- 8: **Beyond Convex Optimization**: Can linear algebra be replaced by algebraic geometry in a systematic way?
- 9: **What are the Physical Consequences of Perelman's Proof of Thurston's Geometrization Theorem?** Can profound theoretical advances in understanding three dimensions be applied to construct and manipulate structures across scales to fabricate novel materials?
- 10: **Algorithmic Origami and Biology**: Build a stronger mathematical theory for isometric and rigid embedding that can give insight into **protein folding**.
- 11: **Optimal Nanostructures**: Develop new mathematics for constructing optimal globally symmetric structures by following simple local rules via the process of **nanoscale self-assembly**.
- 12: **The Mathematics of Quantum Computing, Algorithms, and Entanglement**: In the last century we learned how quantum phenomena shape our world. In the coming century we need to develop the mathematics required to control the quantum world.
- 13: **Creating a Game Theory that Scales**: What new scalable mathematics is needed to replace the traditional Partial Differential Equations (PDE) approach to differential games?

DARPA's Mathematical Challenges

- 14: [An Information Theory for Virus Evolution](#): Can Shannon's theory shed light on this fundamental area of biology?
- 15: The [Geometry of Genome](#) Space: What notion of distance is needed to incorporate biological utility?
- 16: [What are the Symmetries and Action Principles for Biology?](#) Extend our understanding of symmetries and action principles in biology along the lines of classical thermodynamics, to include important biological concepts such as robustness, modularity, evolvability and variability.
- 17: [Geometric Langlands and Quantum Physics](#): How does the Langlands program, which originated in number theory and representation theory, explain the fundamental symmetries of physics? And vice versa?
- 18: [Arithmetic Langlands, Topology, and Geometry](#): What is the role of homotopy theory in the classical, geometric, and quantum Langlands programs?
- 19: [Settle the Riemann Hypothesis](#): The Holy Grail of number theory.
- 20: [Computation at Scale](#): How can we develop asymptotics for a world with massively many degrees of freedom?
- 21: [Settle the Hodge Conjecture](#): This conjecture in algebraic geometry is a metaphor for transforming transcendental computations into algebraic ones.

DARPA's Mathematical Challenges

22: [Settle the Smooth Poincare Conjecture in Dimension 4](#): What are the implications for space-time and cosmology? And might the answer unlock the secret of “dark energy”?

23: [What are the Fundamental **Laws of Biology?**](#) This question will remain front and center for the next 100 years. DARPA places this challenge last as finding these laws will undoubtedly require the mathematics developed in answering several of the questions listed above.

Historical Perspectives

Kurt Gödel (1906-1978)

- Logician, mathematician, and philosopher
- Proved **completeness of predicate logic** and **Gödel's incompleteness theorem**
- Proved consistency of **axiom of choice** and the **continuum hypothesis**
- Invented “**Gödel numbering**” and “**Gödel fuzzy logic**”
- Developed “**Gödel metric**” and paradoxical relativity solutions: “**Gödel spacetime / universe**”
- Made enormous impact on logic, mathematics, and science

Library of Congress

Kurt Gödel
1906-1978

Gödel's Incompleteness Theorem

Frege & Russell:

- Mechanically verifying proofs
- Automatic theorem proving

A set of axioms is:

- **Sound**: iff only true statements can be proved
- **Complete**: iff any statement **or** its negation can be proved
- **Consistent**: iff no statement **and** its negation can be proved

Hilbert's program: find an axiom set for **all** of mathematics
i.e., find a axiom set that is **consistent and complete**

Gödel: any **consistent axiomatic system** is **incomplete!**

(as long as it subsume elementary arithmetic)

i.e., any **consistent** axiomatic system must contain **true** but **unprovable** statements

Mathematical surprise: **truth** and **provability** are **not the same!**

Gödel's Incompleteness Theorem

That **some** axiomatic systems are **incomplete** is **not surprising**, since an important axiom may be missing (e.g., Euclidean geometry without the parallel postulate)

However, that **every** consistent axiomatic system must be **incomplete** was an **unexpected shock** to mathematics!

This **undermined** not only a particular system (e.g., logic), but **axiomatic reasoning** and human thinking itself!

Truth = Provability

Justice ≠ Legality

Gödel's Incompleteness Theorem

Gödel: **consistency** or **completeness** - pick one!

Which is **more important**?

Incomplete: not all true statements can be proved.
But if useful theorems arise, the system is **still useful**.

Inconsistent: some false statement can be proved.
This can be **catastrophic** to the theory:

E.g., supposed in an axiomatic system we proved that “**1=2**”.
Then we can use this to prove that, e.g., all things are equal!

Consider the set: $\{\text{Trump}, \text{Pope}\}$
 $|\{\text{Trump}, \text{Pope}\}| = 2$
 $\Rightarrow |\{\text{Trump}, \text{Pope}\}| = 1$ (since **1=2**)
 $\Rightarrow \text{Trump} = \text{Pope}$ QED

\Rightarrow All things become true: system is “**complete**” but **useless**!

Gödel's Incompleteness Theorem

Moral: it is better to be **consistent** than **complete**,
If you can not be both.

“It is better to be **feared** than **loved**, if you cannot be both.”
- Niccolo Machiavelli (1469-1527), “The Prince”

“You can have it **good**, **cheap**, or **fast** – pick any two.”
- Popular business adage

Gödel's Incompleteness Theorem

Thm: any **consistent** axiomatic system is **incomplete!**

Proof idea:

- Every formula is encoded uniquely as an integer
- Extend “**Gödel numbering**” to formula sequences (proofs)
- Construct a “**proof checking**” formula $P(n,m)$ such that $P(n,m)$ iff n encodes a proof of the formula encoded by m
- Construct a **self-referential** formula that **asserts its own non-provability**: “**I am not provable**”
- Show this formula is **neither provable nor disprovable**

George Boolos (1989) gave shorter proof based on formalizing **Berry's paradox**

The set of true statements is not R.E.!

Diagonalization!
Algorithm!

^{APX}
MEMORY SCHOOL

"YOU SIMPLY ASSOCIATE EACH NUMBER WITH A WORD, SUCH AS 'TABLE' AND 3,476,029."

Gödel's Incompleteness Theorem

Systems known to be **complete** and **consistent**:

- **Propositional logic** (Boolean algebra)
- **Predicate calculus** (first-order logic) [Gödel, 1930]
- Sentential calculus [Bernays, 1918; Post, 1921]
- Presburger arithmetic (also decidable)

Systems known to be either **inconsistent** or **incomplete**:

- Peano arithmetic
- Primitive recursive arithmetic
- Zermelo–Frankel **set theory**
- **Second-order logic**

Q: Is our mathematics both **consistent** and **complete**?

A: No [Gödel, 1931]

Q: Is our mathematics at least **consistent**?

A: We **don't know!** But we sure hope so.

Gödel's "Ontological Proof" that God exists!

Formalized Saint Anselm's ontological argument using modal logic:

- Ax. 1. $P(\varphi) \wedge \Box \forall x[\varphi(x) \rightarrow \psi(x)] \rightarrow P(\psi)$
- Ax. 2. $P(\neg\varphi) \leftrightarrow \neg P(\varphi)$
- Th. 1. $P(\varphi) \rightarrow \Diamond \exists x [\varphi(x)]$
- Df. 1. $G(x) \iff \forall \varphi[P(\varphi) \rightarrow \varphi(x)]$
- Ax. 3. $P(G)$
- Th. 2. $\Diamond \exists x G(x)$
- Df. 2. $\varphi \text{ ess } x \iff \varphi(x) \wedge \forall \psi\{\psi(x) \rightarrow \Box \forall x[\varphi(x) \rightarrow \psi(x)]\}$
- Ax. 4. $P(\varphi) \rightarrow \Box P(\varphi)$
- Th. 3. $G(x) \rightarrow G \text{ ess } x$
- Df. 3. $E(x) \iff \forall \varphi[\varphi \text{ ess } x \rightarrow \Box \exists x \varphi(x)]$
- Ax. 5. $P(E)$
- Th. 4. $\Box \exists x G(x)$

Welcome

The Kurt Gödel Society was founded in 1987 and is chartered in Vienna. It is an international organization for the promotion of research in the areas of Logic, Philosophy, History of Mathematics, above all in connection with the biography of Kurt Gödel, and in other areas to which Gödel made contributions, especially mathematics, physics, theology, philosophy and Leibniz studies.

Horizons of Truth

Logics, Foundations of Mathematics, and the Quest for Understanding the Nature of Knowledge

Gödel Centenary 2006

An International Symposium Celebrating the 100th Birthday of Kurt Gödel

27.-29. April 2006

Festsaal of the University of Vienna

Organized by the [Kurt Gödel Society](#) with the support of the [John Templeton Foundation](#). Co-organized by the [University of Vienna](#), the [Institute for Experimental Physics](#), the [Kurt Gödel Research Center](#), the [Institute Vienna Circle](#), and the [Vienna University of Technology](#).

The purpose of the Symposium is to commemorate the life, work, and foundational views of Kurt Gödel, perhaps the greatest logician of the twentieth century. In the spirit of Gödel's work, the Symposium will also explore current research advances and ideas for future possibilities in the fields of the foundations of mathematics and logic. The symposium intends to put Gödel's ideas and works into a more general context in the light of current understanding and perception. The symposium will also present various implications of his work for other areas of intellectual endeavor such as artificial intelligence, cosmology, philosophy, and theology.

The Symposium will take place 27-29 April in the Celebration Hall of the University of Vienna, famous for its architectural beauty and the murals of Klimt. More than 20 lectures by eminent scientists in the fields of logics, mathematics, philosophy, physics, and theology will provide new insights into the life and work of Kurt Gödel and their implications for future generations.

Church's Thesis
After 70 Years

THE CALCULI OF
LAMBDA-CONVERSION

ALONZO CHURCH

LAST NIGHT I DRIFTED OFF
WHILE READING A LISP BOOK.

SUDDENLY, I WAS BATHED
IN A SUFFUSION OF BLUE.

AT ONCE, JUST LIKE THEY SAID, I FELT A
GREAT ENLIGHTENMENT. I SAW THE NAKED
STRUCTURE OF LISP CODE UNFOLD BEFORE ME.

THE PATTERNS AND METAPATTERNS DANCED.
SYNTAX FADED, AND I SWAM IN THE PURITY OF
QUANTIFIED CONCEPTION. OF IDEAS MANIFEST.

TRULY, THIS WAS
THE LANGUAGE
FROM WHICH THE
GODS WROUGHT
THE UNIVERSE.

NO, IT'S NOT.

IT'S NOT?

I MEAN, OSTENSIBLY, YES.
HONESTLY, WE HACKED MOST
OF IT TOGETHER WITH PERL.

LISP IS OVER HALF A CENTURY OLD AND IT STILL HAS THIS PERFECT, TIMELESS AIR ABOUT IT.

I WONDER IF THE CYCLES WILL CONTINUE FOREVER.

A FEW CODERS FROM EACH NEW GENERATION RE- DISCOVERING THE LISP ARTS.

THESE ARE YOUR FATHER'S PARENTHESES

ELEGANT WEAPONS

FOR A MORE... CIVILIZED AGE.

A GOD'S LAMENT

SOME SAID THE WORLD SHOULD BE IN PERL;
SOME SAID IN LISP.
NOW, HAVING GIVEN BOTH A WHIRL,
I HELD WITH THOSE WHO FAVORED PERL.
BUT I FEAR WE PASSED TO MEN
A DISAPPOINTING FOUNDING MYTH,
AND SHOULD WE WRITE IT ALL AGAIN,
I'D END IT WITH
A CLOSE-PAREN.

AS YOU KNOW, WE'RE IN THE EIGHTH YEAR OF OUR NORTHERN WARS AGAINST THE HASKELLERS. THERE ARE RUMORS THAT MORE OF OUR TROOPS ARE DEFECTING TO THE OTHER SIDE EVERY DAY...

DON'T BE TEMPTED TO BREAK RANKS!

T ASSURE YOU

Historical Perspectives

Alan Turing (1912-1954)

- Mathematician, logician, cryptanalyst, and founder of computer science
- First to formally define computation / algorithm
- Invented the Turing machine model
 - theoretical basis of all modern computers
- Investigated computational “universality”
- Introduced “definable” real numbers
- Proved undecidability of halting problem
- Originated oracles and the “Turing test”
- Pioneered artificial intelligence
- Anticipated neural networks
- Designed the Manchester Mark 1 (1948)
- Helped break the German Enigma cypher
- Turing Award was created in his honor

ALAN TURING
1912 - 1954

Founder of computer science and cryptographer, whose work was key to breaking the wartime Enigma codes, lived and died here.

Bletchley Park (“Station X”), Bletchley, Buckinghamshire, England
England’s code-breaking and cryptanalysis center during WWII

“Bombe” - electromechanical computer designed by Alan Turing.
Used by British cryptologists to break the German Enigma cipher

1918 First Enigma Patent

The official history of the Enigma starts in 1918, when the German **Arthur Scherbius** filed his first patent for the Enigma coding machine. It is listed as patent number 416219 in the archives of the German *Reichspatentamt* (patent office). Please note the time at which the Enigma was invented: **1918**, just after the First World War, more then 20 years before WWII! The image below clearly shows the coding wheels (rotors) in the centre part of the drawing. Below it is the keyboard and to the right is the lamp panel. At the top left is a counter, used to count the number of letters entered on the keyboard. This counter can still be found on certain Enigma models.

Arthur Scherbius' company **Securitas** was based in Berlin (Germany) and had an office in Amsterdam (The Netherlands). As he wanted to protect his invention outside Germany, he also registered his patent in the USA (1922), Great Britain (1923) and France (1923).

This image is taken from patent number 193,035 that was registered in Great Britain in 1923, long before WWII. It was also registered in a number of other countries, such as France and the USA.

During the 1920s the Enigma was available as a commercial device, available for use by companies and embassies for their confidential messages. Remember that in those days, most companies had to use morse code and radio links for long distance communication. The devices were advertised having over 800.000 possibilities.

In the following years, additional patents with improvements of the coding machine were applied. E.g. in GB Patent 267,482, dated 17 Jan 1927, the *Umkehrwalze* was added and a later patent of 14 Nov 1929 (GB 343,146) claims the addition of the *Ringstellung*, multiple notches, etc. One of the drawings of that patent shows a coding device, that we now know as The Enigma, in great detail.

British PM apologizes for treatment ...

"He truly was one of those individuals we can point to whose unique contribution helped to turn the tide of war," he wrote, adding, "The debt of gratitude he is owed makes it all the more horrifying, therefore, that he was treated so inhumanely."

Turing is considered one of Britain's greatest mathematicians, a genius who is credited with inventing the Bombe, a code-breaking machine that deciphered messages encoded by German Enigma machines during World War II.

He went on to develop the Turing machine, a theory that automatic computation cannot solve all mathematical problems, which is considered the basis of modern computing.

Don't Miss

- [Petition seeks apology for Enigma code-breaker Turing](#)
- [Leaders mark 70th anniversary of WWII](#)

Last month, the curious lack of public recognition for Turing's contribution to the war effort and computing in general motivated computer programmer John Graham-Cumming to campaign on his behalf.

The author of the "Geek Atlas," a travel guide for technology enthusiasts, started an online [petition](#), and soon attracted high-profile signatories including scientist Richard Dawkins, actor Stephen Fry, author Ian McEwan and philosopher A.C. Grayling.

"I was surprised by both the number of people who signed and the fast response from the government," Graham-Cumming told CNN. He said the Prime Minister had called him personally to relay news of the apology.

Stories about calls for a British apology were carried in newspapers in France, Switzerland, Spain, Austria, Portugal Poland and the Czech Republic. Supporters set up an [international petition](#) which attracted more than 10,000 signatures. [E-mail to a friend](#) [Mixx it](#) | [Share](#)

1992: Catholic Church apologizes to Galileo, who died in 1642

In 1610, Century Italian astronomer/mathematician /inventor Galileo Galilei used a a telescope he built to observe the solar system, and deduced that the planets orbit the sun, not the earth.

This contradicted Church teachings, and some of the clergy accused Galileo of heresy. One friar went to the Inquisition, the Church court that investigated charges of heresy, and formally accused Galileo. (In 1600, a man named Giordano Bruno was

convicted of being a heretic for believing that the earth moved around the Sun, and that there were many planets throughout the universe where life existed. Bruno was burnt to death.)

Galileo moved on to other projects. He started writing about ocean tides, but instead of writing a scientific paper, he found it much more interesting to have an imaginary conversation among three fictional characters. One character, who would support Galileo's side of the argument, was brilliant. Another character would be open to either side of the argument. The final character, named Simplicio, was dogmatic and foolish, representing all of Galileo's enemies who ignored any evidence that Galileo was right. Soon, Galileo wrote up a sim dialogue called "Dialogue on the Two Great Systems of the V This book talked about the Copernican system.

"Dialogue" was an immediate hit with the public, but not, of course, with the Church. The pope suspected that he was the model for Simplicio. He ordered the book banned, and also ordered Galileo to appear before the Inquisition in Rome for the crime of teaching the Copernican theory after being ordered not to do so.

Galileo was 68 years old and sick. Threatened with torture, he publicly confessed that he had been wrong to have said that the Earth moves around the Sun. Legend then has it that after his confession, Galileo quietly whispered "And yet, it moves."

Unlike many less famous prisoners, Galileo was allowed to live under house arrest. Until his death in 1642, he continued to investigate science, and even published a book on force and motion after he had become blind.

The Church eventually lifted the ban on Galileo's Dialogue in 1822, when it was common knowledge that the Earth was not the center of the Universe. Still later, there were statements by the Vatican Council in the early 1960's and in 1979 that implied that Galileo was pardoned, and that he had suffered at the hands of the Church. Finally, in 1992, three years after Galileo Galilei's namesake spacecraft had been launched on its way to Jupiter, the Vatican formally and publicly cleared Galileo of any wrongdoing.

Theorem: A late apology is better than no apology.
Corollary: But sooner is better!

Turing's Seminal Paper

“**On Computable Numbers**, with an Application to the Entscheidungsproblem”, Proceedings of the London Mathematical Society, 1937, pp. 230-265.

- One of the **most influential** & significant papers ever!
- First formal model of “**computation**”
- First ever definition of “**algorithm**”
- Invented “**Turing machines**”
- Introduced “computational **universality**”
i.e., “programmable”!
- Proved the **undecidability** of halting problem
- Explicates the **Church-Turing Thesis**

ON COMPUTABLE NUMBERS, WITH AN APPLICATION TO
THE ENTSCHIEDUNGSPROBLEM

By A. M. TURING.

[Received 28 May, 1936.—Read 12 November, 1936.]

The “computable” numbers may be described briefly as the real numbers whose expressions as a decimal are calculable by finite means. Although the subject of this paper is ostensibly the computable *numbers*, it is almost equally easy to define and investigate computable functions of an integral variable or a real or computable variable, computable predicates, and so forth. The fundamental problems involved are, however, the same in each case, and I have chosen the computable numbers for explicit treatment as involving the least cumbersome technique. I hope shortly to give an account of the relations of the computable numbers, functions, and so forth to one another. This will include a development of the theory of functions of a real variable expressed in terms of computable numbers. According to my definition, a number is computable if its decimal can be written down by a machine.

In §§ 9, 10 I give some arguments with the intention of showing that the computable numbers include all numbers which could naturally be regarded as computable. In particular, I show that certain large classes of numbers are computable. They include, for instance, the real parts of all algebraic numbers, the real parts of the zeros of the Bessel functions, the numbers π , e , etc. The computable numbers do not, however, include all definable numbers, and an example is given of a definable number which is not computable.

Although the class of computable numbers is so great, and in many ways similar to the class of real numbers, it is nevertheless enumerable. In § 8 I examine certain arguments which would seem to prove the contrary. By the correct application of one of these arguments, conclusions are reached which are superficially similar to those of Gödel†. These results

have valuable applications. In particular, it is shown (§ 11) that the Hilbertian Entscheidungsproblem can have no solution.

In a recent paper Alonzo Church‡ has introduced an idea of “effective calculability”, which is equivalent to my “computability”, but is very differently defined. Church also reaches similar conclusions about the Entscheidungsproblem‡. The proof of equivalence between “computability” and “effective calculability” is outlined in an appendix to the present paper.

1. *Computing machines.*

We have said that the computable numbers are those whose decimals are calculable by finite means. This requires rather more explicit definition. No real attempt will be made to justify the definitions given until we reach § 9. For the present I shall only say that the justification lies in the fact that the human memory is necessarily limited.

We may compare a man in the process of computing a real number to a machine which is only capable of a finite number of conditions q_1, q_2, \dots, q_n , which will be called “ m -configurations”. The machine is supplied with a “tape” (the analogue of paper) running through it, and divided into sections (called “squares”) each capable of bearing a “symbol”. At any moment there is just one square, say the r -th, bearing the symbol $\mathfrak{S}(r)$ which is “in the machine”. We may call this square the “scanned square”. The symbol on the scanned square may be called the “scanned symbol”. The “scanned symbol” is the only one of which the machine is, so to speak, “directly aware”. However, by altering its m -configuration the machine can effectively remember some of the symbols which it has “seen” (scanned) previously. The possible behaviour of the machine at any moment is determined by the m -configuration q_n and the scanned symbol $\mathfrak{S}(r)$. This pair $q_n, \mathfrak{S}(r)$ will be called the “configuration”: thus the configuration determines the possible behaviour of the machine. In some of the configurations in which the scanned square is blank (*i.e.* bears no symbol) the machine writes down a new symbol on the scanned square: in other configurations it erases the scanned symbol. The machine may also change the square which is being scanned, but only by shifting it one place to right or left. In addition to any of these operations the m -configuration may be changed. Some of the symbols written down

† Alonzo Church, “An unsolvable problem of elementary number theory”, *American J. of Math.*, 58 (1936), 345–363.

† Gödel, “Über formal unentscheidbare Sätze der Principia Mathematica und verwandter Systeme, I”, *Monatshfte Math. Phys.*, 38 (1931), 173–198.

will form the sequence of figures which is the decimal of the real number which is being computed. The others are just rough notes to "assist the memory". It will only be these rough notes which will be liable to erasure.

It is my contention that these operations include all those which are used in the computation of a number. The defence of this contention will be easier when the theory of the machines is familiar to the reader. In the next section I therefore proceed with the development of the theory and assume that it is understood what is meant by "machine", "tape", "scanned", etc.

Turing

~~Automatic~~ machines.

2. Definitions.

If at each stage the motion of a machine (in the sense of §1) is *completely* determined by the configuration, we shall call the machine an "automatic machine" (or *a-machine*).

For some purposes we might use machines (choice machines or *c-machines*) whose motion is only partially determined by the configuration (hence the use of the word "possible" in §1). When such a machine reaches one of these ambiguous configurations, it cannot go on until some arbitrary choice has been made by an external operator. This would be the case if we were using machines to deal with axiomatic systems. In this paper I deal only with automatic machines, and will therefore often omit the prefix *a-*.

Computing machines.

If an *a-machine* prints two kinds of symbols, of which the first kind (called figures) consists entirely of 0 and 1 (the others being called symbols of the second kind), then the machine will be called a computing machine. If the machine is supplied with a blank tape and set in motion, starting from the correct initial *m*-configuration, the subsequence of the symbols printed by it which are of the first kind will be called the *sequence computed by the machine*. The real number whose expression as a binary decimal is obtained by prefixing this sequence by a decimal point is called the *number computed by the machine*.

At any stage of the motion of the machine, the number of the scanned square, the complete sequence of all symbols on the tape, and the *m*-configuration will be said to describe the *complete configuration* at that stage. The changes of the machine and tape between successive complete configurations will be called the *moves* of the machine.

Circular and circle-free machines.

If a computing machine never writes down more than a finite number of symbols of the first kind, it will be called *circular*. Otherwise it is said to be *circle-free*.

A machine will be circular if it reaches a configuration from which there is no possible move, or if it goes on moving, and possibly printing symbols of the second kind, but cannot print any more symbols of the first kind. The significance of the term "circular" will be explained in §8.

Computable sequences and numbers.

A sequence is said to be computable if it can be computed by a circle-free machine. A number is computable if it differs by an integer from the number computed by a circle-free machine.

We shall avoid confusion by speaking more often of computable sequences than of computable numbers.

3. Examples of computing machines.

I. A machine can be constructed to compute the sequence 010101... The machine is to have the four *m*-configurations "b", "c", "f", "e" and is capable of printing "0" and "1". The behaviour of the machine is described in the following table in which "*R*" means "the machine moves so that it scans the square immediately on the right of the one it was scanning previously". Similarly for "*L*". "*E*" means "the scanned symbol is erased" and "*P*" stands for "prints". This table (and all succeeding tables of the same kind) is to be understood to mean that for a configuration described in the first two columns the operations in the third column are carried out successively, and the machine then goes over into the *m*-configuration described in the last column. When the second column is left blank, it is understood that the behaviour of the third and fourth columns applies for any symbol and for no symbol. The machine starts in the *m*-configuration b with a blank tape.

Configuration		Behaviour	
<i>m</i> -config.	symbol	operations	final <i>m</i> -config.
b	None	<i>P0, R</i>	c
c	None	<i>R</i>	c
c	None	<i>P1, R</i>	f
f	None	<i>R</i>	b

and each small Greek letter by a symbol, we obtain the table for an m -configuration.

The skeleton tables are to be regarded as nothing but abbreviations: they are not essential. So long as the reader understands how to obtain the complete tables from the skeleton tables, there is no need to give any exact definitions in this connection.

Let us consider an example:

m -config.	Symbol	Behaviour	Final m -config.	
$f(\mathcal{C}, \mathfrak{B}, a)$	\emptyset	L	$f_1(\mathcal{C}, \mathfrak{B}, a)$	From the m -configuration $f(\mathcal{C}, \mathfrak{B}, a)$ the machine finds the symbol of form a which is farthest to the left (the "first a ")
	not \emptyset	L	$f(\mathcal{C}, \mathfrak{B}, a)$	
$f_1(\mathcal{C}, \mathfrak{B}, a)$	a		\mathcal{C}	and the m -configuration then becomes \mathcal{C} . If there is no a then the m -configuration becomes \mathfrak{B} .
	not a	R	$f_1(\mathcal{C}, \mathfrak{B}, a)$	
	None	R	$f_2(\mathcal{C}, \mathfrak{B}, a)$	
$f_2(\mathcal{C}, \mathfrak{B}, a)$	a		\mathcal{C}	
	not a	R	$f_1(\mathcal{C}, \mathfrak{B}, a)$	
	None	R	\mathfrak{B}	

If we were to replace \mathcal{C} throughout by q (say), \mathfrak{B} by r , and a by x , we should have a complete table for the m -configuration $f(q, r, x)$. f is called an " m -configuration function" or " m -function".

The only expressions which are admissible for substitution in an m -function are the m -configurations and symbols of the machine. These have to be enumerated more or less explicitly: they may include expressions such as $p(r, x)$; indeed they must if there are any m -functions used at all. If we did not insist on this explicit enumeration, but simply stated that the machine had certain m -configurations (enumerated) and all m -configurations obtainable by substitution of m -configurations in certain m -functions, we should usually get an infinity of m -configurations; e.g., we might say that the machine was to have the m -configuration q and all m -configurations obtainable by substituting an m -configuration for \mathcal{C} in $p(\mathcal{C})$. Then it would have $q, p(q), p(p(q)), p(p(p(q))), \dots$ as m -configurations.

Our interpretation rule then is this. We are given the names of the m -configurations of the machine, mostly expressed in terms of m -functions. We are also given skeleton tables. All we want is the complete table for the m -configurations of the machine. This is obtained by repeated substitution in the skeleton tables.

Further examples.

(In the explanations the symbol " \rightarrow " is used to signify "the machine goes into the m -configuration. . . .")

$c(\mathcal{C}, \mathfrak{B}, a)$	$f(c_1(\mathcal{C}, \mathfrak{B}, a), \mathfrak{B}, a)$	From $c(\mathcal{C}, \mathfrak{B}, a)$ the first a is erased and $\rightarrow \mathcal{C}$. If there is no $a \rightarrow \mathfrak{B}$.
$c_1(\mathcal{C}, \mathfrak{B}, a)$	$E \quad \mathcal{C}$	
$c(\mathfrak{B}, a)$	$c(c(\mathfrak{B}, a), \mathfrak{B}, a)$	From $c(\mathfrak{B}, a)$ all letters a are erased and $\rightarrow \mathfrak{B}$.

The last example seems somewhat more difficult to interpret than most. Let us suppose that in the list of m -configurations of some machine there appears $c(b, x)$ ($= q$, say). The table is

	$c(b, x)$	$c(c(b, x), b, x)$
or	q	$c(q, b, x)$.
Or, in greater detail:		
	q	$c(q, b, x)$
	$c(q, b, x)$	$f(c_1(q, b, x), b, x)$
	$c_1(q, b, x)$	$E \quad q$.

In this we could replace $c_1(q, b, x)$ by q' and then give the table for f (with the right substitutions) and eventually reach a table in which no m -functions appeared.

$pc(\mathcal{C}, \beta)$	$f(pc_1(\mathcal{C}, \beta), \mathcal{C}, \emptyset)$	From $pc(\mathcal{C}, \beta)$ the machine prints β at the end of the sequence of symbols and $\rightarrow \mathcal{C}$.
$pc_1(\mathcal{C}, \beta)$	Any R, R	$pc_1(\mathcal{C}, \beta)$
	None $P\beta$	\mathcal{C}
$l(\mathcal{C})$	L	\mathcal{C}
$r(\mathcal{C})$	R	\mathcal{C}
$f'(\mathcal{C}, \mathfrak{B}, a)$	$f(l(\mathcal{C}), \mathfrak{B}, a)$	From $f'(\mathcal{C}, \mathfrak{B}, a)$ it does the same as for $f(\mathcal{C}, \mathfrak{B}, a)$ but moves to the left before $\rightarrow \mathcal{C}$.
$f''(\mathcal{C}, \mathfrak{B}, a)$	$f(r(\mathcal{C}), \mathfrak{B}, a)$	
$c(\mathcal{C}, \mathfrak{B}, a)$	$f'(c_1(\mathcal{C}), \mathfrak{B}, a)$	$c(\mathcal{C}, \mathfrak{B}, a)$. The machine writes at the end the first symbol marked a and $\rightarrow \mathcal{C}$.
$c_1(\mathcal{C})$	β	$pc(\mathcal{C}, \beta)$

The last line stands for the totality of lines obtainable from it by replacing β by any symbol which may occur on the tape of the machine concerned.

$cc(\mathbb{C}, \mathfrak{B}, a)$	$c(c(\mathbb{C}, \mathfrak{B}, a), \mathfrak{B}, a)$	$cc(\mathfrak{B}, a)$. The machine copies down in order at the end all symbols marked a and erases the letters a ; $\rightarrow \mathfrak{B}$.
$cc(\mathfrak{B}, a)$	$cc(cc(\mathfrak{B}, a), \mathfrak{B}, a)$	
$rc(\mathbb{C}, \mathfrak{B}, a, \beta)$	$f(rc_1(\mathbb{C}, \mathfrak{B}, a, \beta), \mathfrak{B}, a)$	$rc(\mathbb{C}, \mathfrak{B}, a, \beta)$. The machine replaces the first a by β and $\rightarrow \mathbb{C} \rightarrow \mathfrak{B}$ if there is no a .
$rc_1(\mathbb{C}, \mathfrak{B}, a, \beta)$	$E, P\beta$ \mathbb{C}	
$rc(\mathfrak{B}, a, \beta)$	$rc(rc(\mathfrak{B}, a, \beta), \mathfrak{B}, a, \beta)$	$rc(\mathfrak{B}, a, \beta)$. The machine replaces all letters a by β ; $\rightarrow \mathfrak{B}$.
$cr(\mathbb{C}, \mathfrak{B}, a)$	$c(rc(\mathbb{C}, \mathfrak{B}, a, a), \mathfrak{B}, a)$	$cr(\mathfrak{B}, a)$ differs from $cc(\mathfrak{B}, a)$ only in that the letters a are not erased. The m -configuration $cr(\mathfrak{B}, a)$ is taken up when no letters " a " are on the tape.
$cr(\mathfrak{B}, a)$	$cr(cr(\mathfrak{B}, a), rc(\mathfrak{B}, a, a), a)$	

$cc(\mathbb{C}, \mathfrak{A}, \mathbb{C}, a, \beta)$	$f'(cp_1(\mathbb{C}_1 \mathfrak{A}, \beta), f(\mathfrak{A}, \mathbb{C}, \beta), a)$
$cp_1(\mathbb{C}, \mathfrak{A}, \beta)$	γ $f'(cp_2(\mathbb{C}, \mathfrak{A}, \gamma), \mathfrak{A}, \beta)$
$cp_2(\mathbb{C}, \mathfrak{A}, \gamma)$	$\begin{cases} \gamma & \mathbb{C} \\ \text{not } \gamma & \mathfrak{A}. \end{cases}$

The first symbol marked a and the first marked β are compared. If there is neither a nor β , $\rightarrow \mathbb{C}$. If there are both and the symbols are alike, $\rightarrow \mathbb{C}$. Otherwise $\rightarrow \mathfrak{A}$.

$$cpc(\mathbb{C}, \mathfrak{A}, \mathbb{C}, a, \beta) \quad cp(c(c(\mathbb{C}, \mathbb{C}, \beta), \mathbb{C}, a), \mathfrak{A}, \mathbb{C}, a, \beta)$$

$cpc(\mathbb{C}, \mathfrak{A}, \mathbb{C}, a, \beta)$ differs from $cp(\mathbb{C}, \mathfrak{A}, \mathbb{C}, a, \beta)$ in that in the case when there is similarity the first a and β are erased.

$$cpc(\mathfrak{A}, \mathbb{C}, a, \beta) \quad cpc(cpc(\mathfrak{A}, \mathbb{C}, a, \beta), \mathfrak{A}, \mathbb{C}, a, \beta).$$

$cpc(\mathfrak{A}, \mathbb{C}, a, \beta)$. The sequence of symbols marked a is compared with the sequence marked β . $\rightarrow \mathbb{C}$ if they are similar. Otherwise $\rightarrow \mathfrak{A}$. Some of the symbols a and β are erased.

$q(\mathbb{C})$	$\begin{cases} \text{Any} & R \\ \text{None} & R \end{cases}$	$q(\mathbb{C})$	$q(\mathbb{C}, a)$. The machine finds the last symbol of form a . $\rightarrow \mathbb{C}$.
$q_1(\mathbb{C})$	$\begin{cases} \text{Any} & R \\ \text{None} & \mathbb{C} \end{cases}$	$q_1(\mathbb{C})$	
$q(\mathbb{C}, a)$		$q(q_1(\mathbb{C}, a))$	
$q_1(\mathbb{C}, a)$	$\begin{cases} a & \mathbb{C} \\ \text{not } a & L \end{cases}$	$q_1(\mathbb{C}, a)$	
$pc_2(\mathbb{C}, a, \beta)$		$pc(pc(\mathbb{C}, \beta), a)$	$pc_2(\mathbb{C}, a, \beta)$. The machine prints $a\beta$ at the end.
$cc_2(\mathfrak{B}, a, \beta)$		$cc(cc(\mathfrak{B}, \beta), a)$	$cc_2(\mathfrak{B}, a, \beta, \gamma)$. The machine copies down at the end first the symbols marked a , then those marked β , and finally those marked γ ; it erases the symbols a, β, γ .
$cc_3(\mathfrak{B}, a, \beta, \gamma)$		$cc(cc_2(\mathfrak{B}, \beta, \gamma), a)$	
$e(\mathbb{C})$	$\begin{cases} \mathfrak{a} & R \\ \text{Not } \mathfrak{a} & L \end{cases}$	$e_1(\mathbb{C})$	From $e(\mathbb{C})$ the marks are erased from all marked symbols. $\rightarrow \mathbb{C}$.
$e_1(\mathbb{C})$	$\begin{cases} \text{Any} & R, E, R \\ \text{None} & \mathbb{C} \end{cases}$	$e_1(\mathbb{C})$	

5. Enumeration of computable sequences.

A computable sequence γ is determined by a description of a machine which computes γ . Thus the sequence 001011011101111... is determined by the table on p. 234, and, in fact, any computable sequence is capable of being described in terms of such a table.

It will be useful to put these tables into a kind of standard form. In the first place let us suppose that the table is given in the same form as the first table, for example, I on p. 233. That is to say, that the entry in the operations column is always of one of the forms $E : E, R : E, L : Pa : Pa, R : Pa, L : R : L$: or no entry at all. The table can always be put into this form by introducing more m -configurations. Now let us give numbers to the m -configurations, calling them q_1, \dots, q_R , as in § 1. The initial m -configuration is always to be called q_1 . We also give numbers to the symbols S_1, \dots, S_m

and, in particular, blank = S_0 , $0 = S_1$, $1 = S_2$. The lines of the table are now of form

<i>m</i> -config.	<i>Symbol</i>	<i>Operations</i>	<i>Final</i> <i>m</i> -config.	
q_i	S_j	PS_k, L	q_m	(N_1)
q_i	S_j	PS_k, R	q_m	(N_2)
q_i	S_j	PS_k	q_m	(N_3)

Lines such as

q_i	S_j	E, R	q_m
-------	-------	--------	-------

are to be written as

q_i	S_j	PS_0, R	q_m
-------	-------	-----------	-------

and lines such as

q_i	S_j	R	q_m
-------	-------	-----	-------

to be written as

q_i	S_j	PS_j, R	q_m
-------	-------	-----------	-------

In this way we reduce each line of the table to a line of one of the forms (N_1) , (N_2) , (N_3) .

From each line of form (N_1) let us form an expression $q_i S_j S_k L q_m$; from each line of form (N_2) we form an expression $q_i S_j S_k R q_m$; and from each line of form (N_3) we form an expression $q_i S_j S_k N q_m$.

Let us write down all expressions so formed from the table for the machine and separate them by semi-colons. In this way we obtain a complete description of the machine. In this description we shall replace q_i by the letter "D" followed by the letter "A" repeated i times, and S_j by "D" followed by "C" repeated j times. This new description of the machine may be called the *standard description* (S.D). It is made up entirely from the letters "A", "C", "D", "L", "R", "N", and from ";".

If finally we replace "A" by "1", "C" by "2", "D" by "3", "L" by "4", "R" by "5", "N" by "6", and ";" by "7" we shall have a description of the machine in the form of an arabic numeral. The integer represented by this numeral may be called a *description number* (D.N) of the machine. The D.N determine the S.D and the structure of the

machine uniquely. The machine whose D.N is n may be described as $\mathcal{M}(n)$.

To each computable sequence there corresponds at least one description number, while to no description number does there correspond more than one computable sequence. The computable sequences and numbers are therefore enumerable.

Let us find a description number for the machine I of § 3. When we rename the m -configurations its table becomes:

q_1	S_0	PS_1, R	q_2
q_2	S_0	PS_0, R	q_3
q_3	S_0	PS_2, R	q_4
q_4	S_0	PS_0, R	q_1

Other tables could be obtained by adding irrelevant lines such as

q_1	S_1	PS_1, R	q_2
-------	-------	-----------	-------

Our first standard form would be

$$q_1 S_0 S_1 R q_2; q_2 S_0 S_0 R q_3; q_3 S_0 S_2 R q_4; q_4 S_0 S_0 R q_1;$$

The standard description is

DADDCRDAA;DAADDRDAAA;

DAAADDCCRDAAAA;DAAAADDRDA;

A description number is

$$31332531173113353111731113322531111731111335317$$

and so is

$$3133253117311335311173111332253111173111133531731323253117$$

A number which is a description number of a circle-free machine will be called a *satisfactory* number. In § 8 it is shown that there can be no general process for determining whether a given number is satisfactory or not.

6. The universal computing machine.

It is possible to invent a single machine which can be used to compute any computable sequence. If this machine \mathcal{U} is supplied with a tape on the beginning of which is written the S.D of some computing machine \mathcal{M} ,

then \mathcal{U} will compute the same sequence as \mathcal{M} . In this section I explain in outline the behaviour of the machine. The next section is devoted to giving the complete table for \mathcal{U} .

Let us first suppose that we have a machine \mathcal{M}' which will write down on the F -squares the successive complete configurations of \mathcal{M} . These might be expressed in the same form as on p. 235, using the second description, (C), with all symbols on one line. Or, better, we could transform this description (as in § 5) by replacing each m -configuration by " D " followed by " A " repeated the appropriate number of times, and by replacing each symbol by " D " followed by " C " repeated the appropriate number of times. The numbers of letters " A " and " C " are to agree with the numbers chosen in § 5, so that, in particular, " 0 " is replaced by " DC ", " 1 " by " DCC ", and the blanks by " D ". These substitutions are to be made after the complete configurations have been put together, as in (C). Difficulties arise if we do the substitution first. In each complete configuration the blanks would all have to be replaced by " D ", so that the complete configuration would not be expressed as a finite sequence of symbols.

If in the description of the machine II of § 3 we replace " \circ " by " DAA ", " \circ " by " $DCCC$ ", " q " by " $DAAA$ ", then the sequence (C) becomes:

$$DA : DCCDCCDAADCCDDC : DCCDCCDAADCCDDC : \dots (C_1)$$

(This is the sequence of symbols on F -squares.)

It is not difficult to see that if \mathcal{M} can be constructed, then so can \mathcal{M}' . The manner of operation of \mathcal{M}' could be made to depend on having the rules of operation (*i.e.*, the S.D) of \mathcal{M} written somewhere within itself (*i.e.* within \mathcal{M}'); each step could be carried out by referring to these rules. We have only to regard the rules as being capable of being taken out and exchanged for others and we have something very akin to the universal machine.

One thing is lacking: at present the machine \mathcal{M}' prints no figures. We may correct this by printing between each successive pair of complete configurations the figures which appear in the new configuration but not in the old. Then (C₁) becomes

$$DDA : 0 : 0 : DCCDCCDAADCCDDC : DCCC. \dots (C_2)$$

It is not altogether obvious that the E -squares leave enough room for the necessary "rough work", but this is, in fact, the case.

The sequences of letters between the colons in expressions such as (C₁) may be used as standard descriptions of the complete configurations. When the letters are replaced by figures, as in § 5, we shall have a numerical

description of the complete configuration, which may be called its description number.

7. Detailed description of the universal machine.

A table is given below of the behaviour of this universal machine. The m -configurations of which the machine is capable are all those occurring in the first and last columns of the table, together with all those which occur when we write out the unabbreviated tables of those which appear in the table in the form of m -functions. *E.g.*, $e(\text{anf})$ appears in the table and is an m -function. Its unabbreviated table is (see p. 239)

$e(\text{anf})$	{	\emptyset	R	$e_1(\text{anf})$
		not \emptyset	L	$e(\text{anf})$
$e_1(\text{anf})$	{	Any	R, E, R	$e_1(\text{anf})$
		None		anf

Consequently $e_1(\text{anf})$ is an m -configuration of \mathcal{U} .

When \mathcal{U} is ready to start work the tape running through it bears on it the symbol \emptyset on an F -square and again \emptyset on the next E -square; after this, on F -squares only, comes the S.D of the machine followed by a double colon ":: $:$ " (a single symbol, on an F -square). The S.D consists of a number of instructions, separated by semi-colons.

Each instruction consists of five consecutive parts

(i) " D " followed by a sequence of letters " A ". This describes the relevant m -configuration.

(ii) " D " followed by a sequence of letters " C ". This describes the scanned symbol.

(iii) " D " followed by another sequence of letters " C ". This describes the symbol into which the scanned symbol is to be changed.

(iv) " L ", " R ", or " N ", describing whether the machine is to move to left, right, or not at all.

(v) " D " followed by a sequence of letters " A ". This describes the final m -configuration.

The machine \mathcal{U} is to be capable of printing " A ", " C ", " D ", " 0 ", " 1 ", " u ", " v ", " w ", " x ", " y ", " z ". The S.D is formed from ":: $:$ ", " A ", " C ", " D ", " L ", " R ", " N ".

Subsidiary skeleton table.

con(\mathbb{C} , a)	$\left\{ \begin{array}{l} \text{Not } A \quad R, R \\ A \quad L, Pa, R \end{array} \right.$	con(\mathbb{C} , a)	con(\mathbb{C} , a). Starting from an F -square, S say, the sequence C of symbols describing a configuration closest on the right of S is marked out with letters a . $\rightarrow \mathbb{C}$.
		con ₁ (\mathbb{C} , a)	
con ₁ (\mathbb{C} , a)	$\left\{ \begin{array}{l} A \quad R, Pa, R \\ D \quad R, Pa, R \end{array} \right.$	con ₁ (\mathbb{C} , a)	
		con ₂ (\mathbb{C} , a)	
con ₂ (\mathbb{C} , a)	$\left\{ \begin{array}{l} C \quad R, Pa, R \\ \text{Not } C \quad R, R \end{array} \right.$	con ₂ (\mathbb{C} , a)	con(\mathbb{C} , \cdot). In the final configuration the machine is scanning the square which is four squares to the right of the last square of C . C is left unmarked.
		\mathbb{C}	

The table for \mathcal{U} .

\mathfrak{b}	$f(\mathfrak{b}_1, \mathfrak{b}_1, ::)$	\mathfrak{b} . The machine prints :DA on the F -squares after :: \rightarrow anf.	
\mathfrak{b}_1	$R, R, P:, R, R, PD, R, R, PA$	anf	
anf	$g(\text{anf}_1, :)$	anf. The machine marks the configuration in the last complete configuration with y . \rightarrow fom.	
anf ₁	con(fom, y)		
fom	$\left\{ \begin{array}{l} ; \quad R, Pz, L \\ z \quad L, L \\ \text{not } z \text{ nor } ; \quad L \end{array} \right.$	con(fmp, x)	fom. The machine finds the last semi-colon not marked with z . It marks this semi-colon with z and the configuration following it with x .
		fom	
		fom	
fmp	$cpc(c(\text{fom}, x, y), \text{sim}, x, y)$	fmp. The machine compares the sequences marked x and y . It erases all letters x and y . \rightarrow sim if they are alike. Otherwise \rightarrow fom.	

anf. Taking the long view, the last instruction relevant to the last configuration is found. It can be recognised afterwards as the instruction following the last semi-colon marked z . \rightarrow sim.

sim	$f'(\text{sim}_1, \text{sim}_1, z)$	sim. The machine marks out the instructions. That part of the instructions which refers to operations to be carried out is marked with u , and the final m -configuration with y . The letters z are erased.	
sim ₁	con(sim ₂ , \cdot)		
sim ₂	$\left\{ \begin{array}{l} A \\ \text{not } A \quad R, Pu, R, R, R \end{array} \right.$	sim ₃	sim ₂
	$\left\{ \begin{array}{l} \text{not } A \quad L, Py \\ A \quad L, Py, R, R, R \end{array} \right.$	e(mf, z)	sim ₃
mf	$g(\text{mf}, :)$	mf. The last complete configuration is marked out into four sections. The configuration is left unmarked. The symbol directly preceding it is marked with x . The remainder of the complete configuration is divided into two parts, of which the first is marked with v and the last with w . A colon is printed after the whole. \rightarrow s \mathfrak{h} .	
mf ₁	$\left\{ \begin{array}{l} \text{not } A \quad R, R \\ A \quad L, L, L, L \end{array} \right.$	mf ₁	mf ₂
	$\left\{ \begin{array}{l} C \quad R, Px, L, L, L \\ : \\ D \quad R, Px, L, L, L \end{array} \right.$	mf ₂	mf ₃
mf ₂	$\left\{ \begin{array}{l} : \\ \text{not } : \quad R, Pv, L, L, L \\ : \end{array} \right.$	mf ₃	mf ₄
	$\left\{ \begin{array}{l} : \\ : \end{array} \right.$	mf ₄	con($\mathfrak{I}(\mathfrak{I}(\text{mf}_5))$, \cdot)
mf ₃	$\left\{ \begin{array}{l} \text{Any} \quad R, Pw, R \\ \text{None} \quad P: \end{array} \right.$	mf ₅	s \mathfrak{h}
s \mathfrak{h}	$f(\text{s}\mathfrak{h}_1, \text{inst}, u)$	s \mathfrak{h} . The instructions (marked u) are examined. If it is found that they involve "Print 0" or "Print 1", then 0: or 1: is printed at the end.	
s \mathfrak{h}_1	L, L, L	s \mathfrak{h}_2	s \mathfrak{h}_2
s \mathfrak{h}_2	$\left\{ \begin{array}{l} D \quad R, R, R, R \\ \text{not } D \end{array} \right.$	s \mathfrak{h}_2	inst
	$\left\{ \begin{array}{l} C \quad R, R \\ \text{not } C \end{array} \right.$	s \mathfrak{h}_4	inst
s \mathfrak{h}_3	$\left\{ \begin{array}{l} C \quad R, R \\ \text{not } C \end{array} \right.$	s \mathfrak{h}_5	pe ₂ (inst, 0, \cdot)
	$\left\{ \begin{array}{l} C \\ \text{not } C \end{array} \right.$	inst	pe ₂ (inst, 1, \cdot)

Basis for the 'stored program' concept!

inst	$g(1(\text{inst}_1), u)$	inst.	The next complete configuration is written down, carrying out the marked instructions. The letters u, v, w, x, y are erased. $\rightarrow \text{anf}$.
inst ₁	$a \quad R, E$	inst ₁ (a)	
inst ₁ (L)	$cc_5(v, v, y, x, u, w)$		
inst ₁ (R)	$cc_5(v, v, x, u, y, w)$		
inst ₁ (N)	$cc_5(v, v, x, y, u, w)$		
ov	$c(\text{anf})$		

8. Application of the diagonal process.

It may be thought that arguments which prove that the real numbers are not enumerable would also prove that the computable numbers and sequences cannot be enumerable*. It might, for instance, be thought that the limit of a sequence of computable numbers must be computable. This is clearly only true if the sequence of computable numbers is defined by some rule.

Or we might apply the diagonal process. "If the computable sequences are enumerable, let α_n be the n -th computable sequence, and let $\phi_n(m)$ be the m -th figure in α_n . Let β be the sequence with $1 - \phi_n(n)$ as its n -th figure. Since β is computable, there exists a number K such that $1 - \phi_n(n) = \phi_K(n)$ all n . Putting $n = K$, we have $1 = 2\phi_K(K)$, i.e. 1 is even. This is impossible. The computable sequences are therefore not enumerable".

The fallacy in this argument lies in the assumption that β is computable. It would be true if we could enumerate the computable sequences by finite means, but the problem of enumerating computable sequences is equivalent to the problem of finding out whether a given number is the D.N of a circle-free machine, and we have no general process for doing this in a finite number of steps. In fact, by applying the diagonal process argument correctly, we can show that there cannot be any such general process.

The simplest and most direct proof of this is by showing that, if this general process exists, then there is a machine which computes β . This proof, although perfectly sound, has the disadvantage that it may leave the reader with a feeling that "there must be something wrong". The proof which I shall give has not this disadvantage, and gives a certain insight into the significance of the idea "circle-free". It depends not on constructing β , but on constructing β' , whose n -th figure is $\phi_n(n)$.

Let us suppose that there is such a process; that is to say, that we can invent a machine \mathcal{Q} which, when supplied with the S.D of any computing machine \mathcal{M} will test this S.D and if \mathcal{M} is circular will mark the S.D with the symbol " u " and if it is circle-free will mark it with " s ". By combining the machines \mathcal{Q} and \mathcal{M} we could construct a machine \mathcal{J} to compute the sequence β' . The machine \mathcal{Q} may require a tape. We may suppose that it uses the E -squares beyond all symbols on F -squares, and that when it has reached its verdict all the rough work done by \mathcal{Q} is erased.

The machine \mathcal{J} has its motion divided into sections. In the first $N-1$ sections, among other things, the integers $1, 2, \dots, N-1$ have been written down and tested by the machine \mathcal{Q} . A certain number, say $R(N-1)$, of them have been found to be the D.N's of circle-free machines. In the N -th section the machine \mathcal{Q} tests the number N . If N is satisfactory, i.e., if it is the D.N of a circle-free machine, then $R(N) = 1 + R(N-1)$ and the first $R(N)$ figures of the sequence of which a D.N is N are calculated. The $R(N)$ -th figure of this sequence is written down as one of the figures of the sequence β' computed by \mathcal{J} . If N is not satisfactory, then $R(N) = R(N-1)$ and the machine goes on to the $(N+1)$ -th section of its motion.

From the construction of \mathcal{J} we can see that \mathcal{J} is circle-free. Each section of the motion of \mathcal{J} comes to an end after a finite number of steps. For, by our assumption about \mathcal{Q} , the decision as to whether N is satisfactory is reached in a finite number of steps. If N is not satisfactory, then the N -th section is finished. If N is satisfactory, this means that the machine $\mathcal{M}(N)$ whose D.N is N is circle-free, and therefore its $R(N)$ -th figure can be calculated in a finite number of steps. When this figure has been calculated and written down as the $R(N)$ -th figure of β' , the N -th section is finished. Hence \mathcal{J} is circle-free.

Now let K be the D.N of \mathcal{J} . What does \mathcal{J} do in the K -th section of its motion? It must test whether K is satisfactory, giving a verdict " s " or " u ". Since K is the D.N of \mathcal{J} and since \mathcal{J} is circle-free, the verdict cannot be " u ". On the other hand the verdict cannot be " s ". For if it were, then in the K -th section of its motion \mathcal{J} would be bound to compute the first $R(K-1)+1 = R(K)$ figures of the sequence computed by the machine with K as its D.N and to write down the $R(K)$ -th as a figure of the sequence computed by \mathcal{J} . The computation of the first $R(K)-1$ figures would be carried out all right, but the instructions for calculating the $R(K)$ -th would amount to "calculate the first $R(K)$ figures computed by \mathcal{H} and write down the $R(K)$ -th". This $R(K)$ -th figure would never be found. I.e., \mathcal{J} is circular, contrary both to what we have found in the last paragraph and to the verdict " s ". Thus both verdicts are impossible and we conclude that there can be no machine \mathcal{Q} .

* Cf. Hobson, *Theory of functions of a real variable* (2nd ed., 1921), 87, 88.

We can show further that *there can be no machine \mathcal{E} which, when supplied with the S.D of an arbitrary machine \mathcal{M} , will determine whether \mathcal{M} ever prints a given symbol (0 say).*

We will first show that, if there is a machine \mathcal{E} , then there is a general process for determining whether a given machine \mathcal{M} prints 0 infinitely often. Let \mathcal{M}_1 be a machine which prints the same sequence as \mathcal{M} , except that in the position where the first 0 printed by \mathcal{M} stands, \mathcal{M}_1 prints $\bar{0}$. \mathcal{M}_2 is to have the first two symbols 0 replaced by $\bar{0}$, and so on. Thus, if \mathcal{M} were to print

$$A B A 0 1 A A B 0 0 1 0 A B \dots,$$

then \mathcal{M}_1 would print

$$A B A \bar{0} 1 A A B 0 0 1 0 A B \dots$$

and \mathcal{M}_2 would print

$$A B A \bar{0} 1 A A B \bar{0} 0 1 0 A B \dots$$

Now let \mathcal{E} be a machine which, when supplied with the S.D of \mathcal{M} , will write down successively the S.D of \mathcal{M} , of \mathcal{M}_1 , of \mathcal{M}_2 , ... (there is such a machine). We combine \mathcal{E} with \mathcal{E} and obtain a new machine, \mathcal{G} . In the motion of \mathcal{G} first \mathcal{E} is used to write down the S.D of \mathcal{M} , and then \mathcal{E} tests it: 0 is written if it is found that \mathcal{M} never prints 0; then \mathcal{E} writes the S.D of \mathcal{M}_1 , and this is tested, 0 being printed if and only if \mathcal{M}_1 never prints 0, and so on. Now let us test \mathcal{G} with \mathcal{E} . If it is found that \mathcal{G} never prints 0, then \mathcal{M} prints 0 infinitely often; if \mathcal{G} prints 0 sometimes, then \mathcal{M} does not print 0 infinitely often.

Similarly there is a general process for determining whether \mathcal{M} prints 1 infinitely often. By a combination of these processes we have a process for determining whether \mathcal{M} prints an infinity of figures, *i.e.* we have a process for determining whether \mathcal{M} is circle-free. There can therefore be no machine \mathcal{E} .

The expression "there is a general process for determining ..." has been used throughout this section as equivalent to "there is a machine which will determine ...". This usage can be justified if and only if we can justify our definition of "computable". For each of these "general process" problems can be expressed as a problem concerning a general process for determining whether a given integer n has a property $G(n)$ [*e.g.* $G(n)$ might mean " n is satisfactory" or " n is the Gödel representation of a provable formula"], and this is equivalent to computing a number whose n -th figure is 1 if $G(n)$ is true and 0 if it is false.

9. The extent of the computable numbers.

No attempt has yet been made to show that the "computable" numbers include all numbers which would naturally be regarded as computable. All arguments which can be given are bound to be, fundamentally, appeals to intuition, and for this reason rather unsatisfactory mathematically. The real question at issue is "What are the possible processes which can be carried out in computing a number?"

The arguments which I shall use are of three kinds.

(a) A direct appeal to intuition.

(b) A proof of the equivalence of two definitions (in case the new definition has a greater intuitive appeal).

(c) Giving examples of large classes of numbers which are computable.

Once it is granted that computable numbers are all "computable", several other propositions of the same character follow. In particular, it follows that, if there is a general process for determining whether a formula of the Hilbert function calculus is provable, then the determination can be carried out by a machine.

I. [Type (a)]. This argument is only an elaboration of the ideas of § 1.

Computing is normally done by writing certain symbols on paper. We may suppose this paper is divided into squares like a child's arithmetic book. In elementary arithmetic the two-dimensional character of the paper is sometimes used. But such a use is always avoidable, and I think that it will be agreed that the two-dimensional character of paper is no essential of computation. I assume then that the computation is carried out on one-dimensional paper, *i.e.* on a tape divided into squares. I shall also suppose that the number of symbols which may be printed is finite. If we were to allow an infinity of symbols, then there would be symbols differing to an arbitrarily small extent[†]. The effect of this restriction of the number of symbols is not very serious. It is always possible to use sequences of symbols in the place of single symbols. Thus an Arabic numeral such as

[†] If we regard a symbol as literally printed on a square we may suppose that the square is $0 < x < 1$, $0 < y < 1$. The symbol is defined as a set of points in this square, *viz.* the set occupied by printer's ink. If these sets are restricted to be measurable, we can define the "distance" between two symbols as the cost of transforming one symbol into the other if the cost of moving unit area of printer's ink unit distance is unity, and there is an infinite supply of ink at $x = 2$, $y = 0$. With this topology the symbols form a conditionally compact space.

17 or 9999999999999999 is normally treated as a single symbol. Similarly in any European language words are treated as single symbols (Chinese, however, attempts to have an enumerable infinity of symbols). The differences from our point of view between the single and compound symbols is that the compound symbols, if they are too lengthy, cannot be observed at one glance. This is in accordance with experience. We cannot tell at a glance whether 9999999999999999 and 9999999999999999 are the same.

The behaviour of the computer at any moment is determined by the symbols which he is observing, and his "state of mind" at that moment.

We may suppose that there is a bound B to the number of symbols or squares which the computer can observe at one moment. If he wishes to observe more, he must use successive observations. We will also suppose that the number of states of mind which need be taken into account is finite. The reasons for this are of the same character as those which restrict the number of symbols. If we admitted an infinity of states of mind, some of them will be "arbitrarily close" and will be confused. Again, the restriction is not one which seriously affects computation, since the use of more complicated states of mind can be avoided by writing more symbols on the tape.

Let us imagine the operations performed by the computer to be split up into "simple operations" which are so elementary that it is not easy to imagine them further divided. Every such operation consists of some change of the physical system consisting of the computer and his tape. We know the state of the system if we know the sequence of symbols on the tape, which of these are observed by the computer (possibly with a special order), and the state of mind of the computer. We may suppose that in a simple operation not more than one symbol is altered. Any other changes can be split up into simple changes of this kind. The situation in regard to the squares whose symbols may be altered in this way is the same as in regard to the observed squares. We may, therefore, without loss of generality, assume that the squares whose symbols are changed are always "observed" squares.

Besides these changes of symbols, the simple operations must include changes of distribution of observed squares. The new observed squares must be immediately recognisable by the computer. I think it is reasonable to suppose that they can only be squares whose distance from the closest of the immediately previously observed squares does not exceed a certain fixed amount. Let us say that each of the new observed squares is within L squares of an immediately previously observed square.

In connection with "immediate recognisability", it may be thought that there are other kinds of square which are immediately recognisable. In particular, squares marked by special symbols might be taken as imme-

diately recognisable. Now if these squares are marked only by single symbols there can be only a finite number of them, and we should not upset our theory by adjoining these marked squares to the observed squares. If, on the other hand, they are marked by a sequence of symbols, we cannot regard the process of recognition as a simple process. This is a fundamental point and should be illustrated. In most mathematical papers the equations and theorems are numbered. Normally the numbers do not go beyond (say) 1000. It is, therefore, possible to recognise a theorem at a glance by its number. But if the paper was very long, we might reach Theorem 157767733443477; then, further on in the paper, we might find "... hence (applying Theorem 157767733443477) we have ...". In order to make sure which was the relevant theorem we should have to compare the two numbers figure by figure, possibly ticking the figures off in pencil to make sure of their not being counted twice. If in spite of this it is still thought that there are other "immediately recognisable" squares, it does not upset my contention so long as these squares can be found by some process of which my type of machine is capable. This idea is developed in III below.

The simple operations must therefore include:

- (a) Changes of the symbol on one of the observed squares.
- (b) Changes of one of the squares observed to another square within L squares of one of the previously observed squares.

It may be that some of these changes necessarily involve a change of state of mind. The most general single operation must therefore be taken to be one of the following:

- (A) A possible change (a) of symbol together with a possible change of state of mind.
- (B) A possible change (b) of observed squares, together with a possible change of state of mind.

The operation actually performed is determined, as has been suggested on p. 250, by the state of mind of the computer and the observed symbols. In particular, they determine the state of mind of the computer after the operation is carried out.

We may now construct a machine to do the work of this computer. To each state of mind of the computer corresponds an " m -configuration" of the machine. The machine scans B squares corresponding to the B squares observed by the computer. In any move the machine can change a symbol on a scanned square or can change any one of the scanned squares to another square distant not more than L squares from one of the other scanned

squares. The move which is done, and the succeeding configuration, are determined by the scanned symbol and the m -configuration. The machines just described do not differ very essentially from computing machines as defined in § 2, and corresponding to any machine of this type a computing machine can be constructed to compute the same sequence, that is to say the sequence computed by the computer.

II. [Type (b)].

If the notation of the Hilbert functional calculus† is modified so as to be systematic, and so as to involve only a finite number of symbols, it becomes possible to construct an automatic‡ machine \mathcal{K} , which will find all the provable formulae of the calculus§.

Now let α be a sequence, and let us denote by $G_\alpha(x)$ the proposition "The x -th figure of α is 1", so that $\neg G_\alpha(x)$ means "The x -th figure of α is 0". Suppose further that we can find a set of properties which define the sequence α and which can be expressed in terms of $G_\alpha(x)$ and of the propositional functions $N(x)$ meaning " x is a non-negative integer" and $F(x, y)$ meaning " $y = x + 1$ ". When we join all these formulae together conjunctively, we shall have a formula, \mathfrak{A} say, which defines α . The terms of \mathfrak{A} must include the necessary parts of the Peano axioms, viz.,

$$(\exists u) N(u) \& (x) (N(x) \rightarrow (\exists y) F(x, y)) \& (F(x, y) \rightarrow N(y)),$$

which we will abbreviate to P .

When we say " \mathfrak{A} defines α ", we mean that $\neg \mathfrak{A}$ is not a provable formula, and also that, for each n , one of the following formulae (A_n) or (B_n) is provable.

$$\mathfrak{A} \& F^{(n)} \rightarrow G_\alpha(u^{(n)}), \quad (A_n) \text{¶}$$

$$\mathfrak{A} \& F^{(n)} \rightarrow (\neg G_\alpha(u^{(n)})), \quad (B_n),$$

where $F^{(n)}$ stands for $F(u, u') \& F(u', u'') \& \dots F(u^{(n-1)}, u^{(n)})$.

† The expression "the functional calculus" is used throughout to mean the *restricted* Hilbert functional calculus.

‡ It is most natural to construct first a choice machine (§ 2) to do this. But it is then easy to construct the required automatic machine. We can suppose that the choices are always choices between two possibilities 0 and 1. Each proof will then be determined by a sequence of choices i_1, i_2, \dots, i_n ($i_1 = 0$ or 1, $i_2 = 0$ or 1, ..., $i_n = 0$ or 1), and hence the number $2^{i_1} + i_1 2^{i_2} + i_2 2^{i_3} + \dots + i_n$ completely determines the proof. The automatic machine carries out successively proof 1, proof 2, proof 3, ...

§ The author has found a description of such a machine.

¶ The negation sign is written before an expression and not over it.

¶ A sequence of r primes is denoted by r .

I say that α is then a computable sequence: a machine \mathcal{K}_α to compute α can be obtained by a fairly simple modification of \mathcal{K} .

We divide the motion of \mathcal{K}_α into sections. The n -th section is devoted to finding the n -th figure of α . After the $(n-1)$ -th section is finished a double colon :: is printed after all the symbols, and the succeeding work is done wholly on the squares to the right of this double colon. The first step is to write the letter "A" followed by the formula (A_n) and then "B" followed by (B_n) . The machine \mathcal{K}_α then starts to do the work of \mathcal{K} , but whenever a provable formula is found, this formula is compared with (A_n) and with (B_n) . If it is the same formula as (A_n) , then the figure "1" is printed, and the n -th section is finished. If it is (B_n) , then "0" is printed and the section is finished. If it is different from both, then the work of \mathcal{K} is continued from the point at which it had been abandoned. Sooner or later one of the formulae (A_n) or (B_n) is reached; this follows from our hypotheses about α and \mathfrak{A} , and the known nature of \mathcal{K} . Hence the n -th section will eventually be finished. \mathcal{K}_α is circle-free; α is computable.

It can also be shown that the numbers α definable in this way by the use of axioms include all the computable numbers. This is done by describing computing machines in terms of the function calculus.

It must be remembered that we have attached rather a special meaning to the phrase " \mathfrak{A} defines α ". The computable numbers do not include all (in the ordinary sense) definable numbers. Let δ be a sequence whose n -th figure is 1 or 0 according as n is or is not satisfactory. It is an immediate consequence of the theorem of § 8 that δ is not computable. It is (so far as we know at present) possible that any assigned number of figures of δ can be calculated, but not by a uniform process. When sufficiently many figures of δ have been calculated, an essentially new method is necessary in order to obtain more figures.

III. This may be regarded as a modification of I or as a corollary of II.

We suppose, as in I, that the computation is carried out on a tape; but we avoid introducing the "state of mind" by considering a more physical and definite counterpart of it. It is always possible for the computer to break off from his work, to go away and forget all about it, and later to come back and go on with it. If he does this he must leave a note of instructions (written in some standard form) explaining how the work is to be continued. This note is the counterpart of the "state of mind". We will suppose that the computer works in such a desultory manner that he never does more than one step at a sitting. The note of instructions must enable him to carry out one step and write the next note. Thus the state of progress of the computation at any stage is completely determined by the note of

instructions and the symbols on the tape. That is, the state of the system may be described by a single expression (sequence of symbols), consisting of the symbols on the tape followed by Δ (which we suppose not to appear elsewhere) and then by the note of instructions. This expression may be called the "state formula". We know that the state formula at any given stage is determined by the state formula before the last step was made, and we assume that the relation of these two formulae is expressible in the functional calculus. In other words, we assume that there is an axiom \mathfrak{A} which expresses the rules governing the behaviour of the computer, in terms of the relation of the state formula at any stage to the state formula at the preceding stage. If this is so, we can construct a machine to write down the successive state formulae, and hence to compute the required number.

10. *Examples of large classes of numbers which are computable.*

It will be useful to begin with definitions of a computable function of an integral variable and of a computable variable, etc. There are many equivalent ways of defining a computable function of an integral variable. The simplest is, possibly, as follows. If γ is a computable sequence in which 0 appears infinitely† often, and n is an integer, then let us define $\xi(\gamma, n)$ to be the number of figures 1 between the n -th and the $(n+1)$ -th figure 0 in γ . Then $\phi(n)$ is computable if, for all n and some γ , $\phi(n) = \xi(\gamma, n)$. An equivalent definition is this. Let $H(x, y)$ mean $\phi(x) = y$. Then, if we can find a contradiction-free axiom \mathfrak{A}_ϕ , such that $\mathfrak{A}_\phi \rightarrow P$, and if for each integer n there exists an integer N , such that

$$\mathfrak{A}_\phi \ \& \ F^{(N)} \rightarrow H(u^{(n)}, u^{(\phi(n))}),$$

and such that, if $m \neq \phi(n)$, then, for some N' ,

$$\mathfrak{A}_\phi \ \& \ F^{(N')} \rightarrow (-H(u^{(n)}, u^{(m)})),$$

then ϕ may be said to be a computable function.

We cannot define general computable functions of a real variable, since there is no general method of describing a real number, but we can define a computable function of a computable variable. If n is satisfactory, let γ_n be the number computed by $\mathfrak{M}(n)$, and let

$$a_n = \tan\left(\pi\left(\gamma_n - \frac{1}{2}\right)\right),$$

† If \mathfrak{M} computes γ , then the problem whether \mathfrak{M} prints 0 infinitely often is of the same character as the problem whether \mathfrak{M} is circle-free.

unless $\gamma_n = 0$ or $\gamma_n = 1$, in either of which cases $a_n = 0$. Then, as n runs through the satisfactory numbers, a_n runs through the computable numbers†. Now let $\phi(n)$ be a computable function which can be shown to be such that for any satisfactory argument its value is satisfactory‡. Then the function f , defined by $f(a_n) = a_{\phi(n)}$, is a computable function and all computable functions of a computable variable are expressible in this form.

Similar definitions may be given of computable functions of several variables, computable-valued functions of an integral variable, etc.

I shall enunciate a number of theorems about computability, but I shall prove only (ii) and a theorem similar to (iii).

(i) A computable function of a computable function of an integral or computable variable is computable.

(ii) Any function of an integral variable defined recursively in terms of computable functions is computable. I.e. if $\phi(m, n)$ is computable, and r is some integer, then $\eta(n)$ is computable, where

$$\eta(0) = r,$$

$$\eta(n) = \phi(n, \eta(n-1)).$$

(iii) If $\phi(m, n)$ is a computable function of two integral variables, then $\phi(n, n)$ is a computable function of n .

(iv) If $\phi(n)$ is a computable function whose value is always 0 or 1, then the sequence whose n -th figure is $\phi(n)$ is computable.

Dedekind's theorem does not hold in the ordinary form if we replace "real" throughout by "computable". But it holds in the following form:

(v) If $G(a)$ is a propositional function of the computable numbers and

$$(a) \quad (\exists \alpha)(\exists \beta) \{ G(\alpha) \ \& \ (-G(\beta)) \},$$

$$(b) \quad G(\alpha) \ \& \ (-G(\beta)) \rightarrow (\alpha < \beta),$$

and there is a general process for determining the truth value of $G(\alpha)$, then

† A function a_n may be defined in many other ways so as to run through the computable numbers.

‡ Although it is not possible to find a general process for determining whether a given number is satisfactory, it is often possible to show that certain classes of numbers are satisfactory.

there is a computable number ξ such that

$$G(a) \rightarrow a \leq \xi, \\ -G(a) \rightarrow a \geq \xi.$$

In other words, the theorem holds for any section of the computables such that there is a general process for determining to which class a given number belongs.

Owing to this restriction of Dedekind's theorem, we cannot say that a computable bounded increasing sequence of computable numbers has a computable limit. This may possibly be understood by considering a sequence such as

$$-1, -\frac{1}{2}, -\frac{1}{4}, -\frac{1}{8}, -\frac{1}{16}, \frac{1}{2}, \dots$$

On the other hand, (v) enables us to prove

(vi) If α and β are computable and $\alpha < \beta$ and $\phi(\alpha) < 0 < \phi(\beta)$, where $\phi(\alpha)$ is a computable increasing continuous function, then there is a unique computable number γ , satisfying $\alpha < \gamma < \beta$ and $\phi(\gamma) = 0$.

Computable convergence.

We shall say that a sequence β_n of computable numbers *converges computably* if there is a computable integral valued function $N(\epsilon)$ of the computable variable ϵ , such that we can show that, if $\epsilon > 0$ and $n > N(\epsilon)$ and $m > N(\epsilon)$, then $|\beta_n - \beta_m| < \epsilon$.

We can then show that

(vii) A power series whose coefficients form a computable sequence of computable numbers is computably convergent at all computable points in the interior of its interval of convergence.

(viii) The limit of a computably convergent sequence is computable.

And with the obvious definition of "uniformly computably convergent":

(ix) The limit of a uniformly computably convergent computable sequence of computable functions is a computable function. Hence

(x) The sum of a power series whose coefficients form a computable sequence is a computable function in the interior of its interval of convergence.

From (viii) and $\pi = 4(1 - \frac{1}{3} + \frac{1}{3^2} - \dots)$ we deduce that π is computable.

From $e = 1 + 1 + \frac{1}{2!} + \frac{1}{3!} + \dots$ we deduce that e is computable.

From (vi) we deduce that all real algebraic numbers are computable.

From (vi) and (x) we deduce that the real zeros of the Bessel functions are computable.

Proof of (ii).

Let $H(x, y)$ mean " $\eta(x) = y$ ", and let $K(x, y, z)$ mean " $\phi(x, y) = z$ ". \mathfrak{A}_ϕ is the axiom for $\phi(x, y)$. We take \mathfrak{A}_η to be

$$\mathfrak{A}_\phi \ \& \ P \ \& \ (F(x, y) \rightarrow G(x, y)) \ \& \ (G(x, y) \ \& \ G(y, z) \rightarrow G(x, z)) \\ \& \ (F^{(r)} \rightarrow H(u, u^{(r)})) \ \& \ (F(v, w) \ \& \ H(v, x) \ \& \ K(w, x, z) \rightarrow H(w, z)) \\ \& \ [H(w, z) \ \& \ G(z, t) \vee G(t, z) \rightarrow (-H(w, t))].$$

I shall not give the proof of consistency of \mathfrak{A}_η . Such a proof may be constructed by the methods used in Hilbert and Bernays, *Grundlagen der Mathematik* (Berlin, 1934), p. 209 *et seq.* The consistency is also clear from the meaning.

Suppose that, for some n, N , we have shown

$$\mathfrak{A}_\eta \ \& \ F^{(N)} \rightarrow H(u^{(n-1)}, u^{(\eta(n-1))}),$$

then, for some M ,

$$\mathfrak{A}_\phi \ \& \ F^{(M)} \rightarrow K(u^{(n)}, u^{(\eta(n-1))}, u^{(\eta(n))}),$$

$$\mathfrak{A}_\eta \ \& \ F^{(M)} \rightarrow F(u^{(n-1)}, u^{(n)}) \ \& \ H(u^{(n-1)}, u^{(\eta(n-1))})$$

$$\ \& \ K(u^{(n)}, u^{(\eta(n-1))}, u^{(\eta(n))}),$$

and

$$\mathfrak{A}_\eta \ \& \ F^{(M)} \rightarrow [F(u^{(n-1)}, u^{(n)}) \ \& \ H(u^{(n-1)}, u^{(\eta(n-1))})$$

$$\ \& \ K(u^{(n)}, u^{(\eta(n-1))}, u^{(\eta(n))}) \rightarrow H(u^{(n)}, u^{(\eta(n))})].$$

Hence

$$\mathfrak{A}_\eta \ \& \ F^{(M)} \rightarrow H(u^{(n)}, u^{(\eta(n))}).$$

Also

$$\mathfrak{A}_\eta \ \& \ F^{(r)} \rightarrow H(u, u^{(\eta(0))}).$$

Hence for each n some formula of the form

$$\mathfrak{A}_\eta \ \& \ F^{(M)} \rightarrow H(u^{(n)}, u^{(\eta(n))})$$

is provable. Also, if $M' \geq M$ and $M' \geq m$ and $m \neq \eta(u)$, then

$$\mathfrak{A}_\eta \ \& \ F^{(M')} \rightarrow G(u^{(\eta(m))}, u^{(m)}) \vee G(u^{(m)}, u^{(\eta(m))})$$

and

$$\mathfrak{A}_\eta \& F^{(M')} \rightarrow \left[\{G(u^{(n)}, u^{(m)}) \vee G(u^{(m)}, u^{(n)})\} \right. \\ \left. \& H(u^{(n)}, u^{(n)})\} \rightarrow (-H(u^{(n)}, u^{(m)})) \right].$$

Hence $\mathfrak{A}_\eta \& F^{(M')} \rightarrow (-H(u^{(m)}, u^{(m)}))$.

The conditions of our second definition of a computable function are therefore satisfied. Consequently η is a computable function.

Proof of a modified form of (iii).

Suppose that we are given a machine \mathfrak{N} , which, starting with a tape bearing on it $\epsilon\epsilon$ followed by a sequence of any number of letters “ F ” on F -squares and in the m -configuration b , will compute a sequence γ_n depending on the number n of letters “ F ”. If $\phi_n(m)$ is the m -th figure of γ_n , then the sequence β whose n -th figure is $\phi_n(n)$ is computable.

We suppose that the table for \mathfrak{N} has been written out in such a way that in each line only one operation appears in the operations column. We also suppose that Ξ , Θ , $\bar{0}$, and $\bar{1}$ do not occur in the table, and we replace ϵ throughout by Θ , 0 by $\bar{0}$, and 1 by $\bar{1}$. Further substitutions are then made. Any line of form

$$\mathfrak{A} \quad a \quad P\bar{0} \quad \mathfrak{B}$$

we replace by

$$\mathfrak{A} \quad a \quad P\bar{0} \quad \text{re}(\mathfrak{B}, u, h, k)$$

and any line of the form

$$\mathfrak{A} \quad a \quad P\bar{1} \quad \mathfrak{B}$$

by

$$\mathfrak{A} \quad a \quad P\bar{1} \quad \text{re}(\mathfrak{B}, v, h, k)$$

and we add to the table the following lines:

$$\begin{array}{lll} u & & \text{pe}(u_1, 0) \\ u_1 & R, Pk, R, P\Theta, R, P\Theta & u_2 \\ u_2 & & \text{re}(u_3, u_3, k, h) \\ u_3 & & \text{pe}(u_2, F) \end{array}$$

and similar lines with v for u and 1 for 0 together with the following line

$$c \quad R, P\Xi, R, Ph \quad \delta.$$

We then have the table for the machine \mathfrak{N}' which computes β . The initial m -configuration is c , and the initial scanned symbol is the second ϵ .

11. Application to the Entscheidungsproblem.

The results of §8 have some important applications. In particular, they can be used to show that the Hilbert Entscheidungsproblem can have no solution. For the present I shall confine myself to proving this particular theorem. For the formulation of this problem I must refer the reader to Hilbert and Ackermann's *Grundzüge der Theoretischen Logik* (Berlin, 1931), chapter 3.

I propose, therefore, to show that there can be no general process for determining whether a given formula \mathfrak{A} of the functional calculus \mathbf{K} is provable, *i.e.* that there can be no machine which, supplied with any one \mathfrak{A} of these formulae, will eventually say whether \mathfrak{A} is provable.

It should perhaps be remarked that what I shall prove is quite different from the well-known results of Gödel†. Gödel has shown that (in the formalism of Principia Mathematica) there are propositions \mathfrak{A} such that neither \mathfrak{A} nor $\neg\mathfrak{A}$ is provable. As a consequence of this, it is shown that no proof of consistency of Principia Mathematica (or of \mathbf{K}) can be given within that formalism. On the other hand, I shall show that there is no general method which tells whether a given formula \mathfrak{A} is provable in \mathbf{K} , or, what comes to the same, whether the system consisting of \mathbf{K} with $\neg\mathfrak{A}$ adjoined as an extra axiom is consistent.

If the negation of what Gödel has shown had been proved, *i.e.* if, for each \mathfrak{A} , either \mathfrak{A} or $\neg\mathfrak{A}$ is provable, then we should have an immediate solution of the Entscheidungsproblem. For we can invent a machine \mathfrak{K} which will prove consecutively all provable formulae. Sooner or later \mathfrak{K} will reach either \mathfrak{A} or $\neg\mathfrak{A}$. If it reaches \mathfrak{A} , then we know that \mathfrak{A} is provable. If it reaches $\neg\mathfrak{A}$, then, since \mathbf{K} is consistent (Hilbert and Ackermann, p. 65), we know that \mathfrak{A} is not provable.

Owing to the absence of integers in \mathbf{K} the proofs appear somewhat lengthy. The underlying ideas are quite straightforward.

Corresponding to each computing machine \mathcal{M} we construct a formula $\text{Un}(\mathcal{M})$ and we show that, if there is a general method for determining whether $\text{Un}(\mathcal{M})$ is provable, then there is a general method for determining whether \mathcal{M} ever prints 0 .

The interpretations of the propositional functions involved are as follows:

$R_S(x, y)$ is to be interpreted as “in the complete configuration x (of \mathcal{M}) the symbol on the square y is S ”.

† *Loc. cit.*

$I(x, y)$ is to be interpreted as "in the complete configuration x the square y is scanned".

$K_{q_m}(x)$ is to be interpreted as "in the complete configuration x the m -configuration is q_m ".

$F(x, y)$ is to be interpreted as " y is the immediate successor of x ".

$\text{Inst}\{q_i S_i S_k L q_l\}$ is to be an abbreviation for

$$\begin{aligned} (x, y, x', y') \left\{ \left(R_{S_i}(x, y) \& I(x, y) \& K_{q_i}(x) \& F(x, x') \& F(y', y) \right) \right. \\ \rightarrow \left(I(x', y') \& R_{S_k}(x', y) \& K_{q_l}(x') \right. \\ \left. \left. \& (z) \left[F(y', z) \vee \left(R_{S_j}(x, z) \rightarrow R_{S_k}(x', z) \right) \right] \right) \right\}. \end{aligned}$$

$\text{Inst}\{q_i S_i S_k R q_l\}$ and $\text{Inst}\{q_i S_i S_k N q_l\}$

are to be abbreviations for other similarly constructed expressions.

Let us put the description of \mathcal{A} into the first standard form of § 6. This description consists of a number of expressions such as " $q_i S_i S_k L q_l$ " (or with R or N substituted for L). Let us form all the corresponding expressions such as $\text{Inst}\{q_i S_i S_k L q_l\}$ and take their logical sum. This we call $\text{Des}(\mathcal{A})$.

The formula $\text{Un}(\mathcal{A})$ is to be

$$\begin{aligned} (\exists u) \left[N(u) \& (x) \left(N(x) \rightarrow (\exists x') F(x, x') \right) \right. \\ \left. \& (y, z) \left(F(y, z) \rightarrow N(y) \& N(z) \right) \& (y) R_{S_0}(u, y) \right. \\ \left. \& I(u, u) \& K_{q_1}(u) \& \text{Des}(\mathcal{A}) \right] \\ \rightarrow (\exists s) (\exists t) [N(s) \& N(t) \& R_{S_1}(s, t)]. \end{aligned}$$

$[N(u) \& \dots \& \text{Des}(\mathcal{A})]$ may be abbreviated to $A(\mathcal{A})$.

When we substitute the meanings suggested on p. 259-60 we find that $\text{Un}(\mathcal{A})$ has the interpretation "in some complete configuration of \mathcal{A} , S_1 (*i.e.* 0) appears on the tape". Corresponding to this I prove that

(a) If S_1 appears on the tape in some complete configuration of \mathcal{A} , then $\text{Un}(\mathcal{A})$ is provable.

(b) If $\text{Un}(\mathcal{A})$ is provable, then S_1 appears on the tape in some complete configuration of \mathcal{A} .

When this has been done, the remainder of the theorem is trivial.

LEMMA 1. If S_1 appears on the tape in some complete configuration of \mathcal{A} , then $\text{Un}(\mathcal{A})$ is provable.

We have to show how to prove $\text{Un}(\mathcal{A})$. Let us suppose that in the n -th complete configuration the sequence of symbols on the tape is $S_{r(n,0)}, S_{r(n,1)}, \dots, S_{r(n,n)}$, followed by nothing but blanks, and that the scanned symbol is the $i(n)$ -th, and that the m -configuration is $q_{k(n)}$. Then we may form the proposition

$$\begin{aligned} R_{S_{r(n,0)}}(u^{(n)}, u) \& R_{S_{r(n,1)}}(u^{(n)}, u') \& \dots \& R_{S_{r(n,n)}}(u^{(n)}, u^{(n)}) \\ \& I(u^{(n)}, u^{(i(n))}) \& K_{q_{k(n)}}(u^{(n)}) \\ \& (y) F \left((y, u') \vee F(u, y) \vee F(u', y) \vee \dots \vee F(u^{(i-1)}, y) \vee R_{S_0}(u^{(n)}, y) \right), \end{aligned}$$

which we may abbreviate to CC_n .

As before, $F(u, u') \& F(u', u'') \& \dots \& F(u^{(r-1)}, u^{(r)})$ is abbreviated to $F^{(r)}$.

I shall show that all formulae of the form $A(\mathcal{A}) \& F^{(n)} \rightarrow CC_n$ (abbreviated to CF_n) are provable. The meaning of CF_n is "The n -th complete configuration of \mathcal{A} is so and so", where "so and so" stands for the actual n -th complete configuration of \mathcal{A} . That CF_n should be provable is therefore to be expected.

CF_0 is certainly provable, for in the complete configuration the symbols are all blanks, the m -configuration is q_1 , and the scanned square is u , *i.e.* CC_0 is

$$(y) R_{S_0}(u, y) \& I(u, u) \& K_{q_1}(u).$$

$A(\mathcal{A}) \rightarrow CC_0$ is then trivial.

We next show that $CF_n \rightarrow CF_{n+1}$ is provable for each n . There are three cases to consider, according as in the move from the n -th to the $(n+1)$ -th configuration the machine moves to left or to right or remains stationary. We suppose that the first case applies, *i.e.* the machine moves to the left. A similar argument applies in the other cases. If $r(n, i(n)) = a$, $r(n+1, i(n+1)) = c$, $k(i(n)) = b$, and $k(i(n+1)) = d$, then $\text{Des}(\mathcal{A})$ must include $\text{Inst}\{q_a S_b S_d L q_c\}$ as one of its terms, *i.e.*

$$\text{Des}(\mathcal{A}) \rightarrow \text{Inst}\{q_a S_b S_d L q_c\}.$$

Hence $A(\mathcal{A}) \& F^{(n+1)} \rightarrow \text{Inst}\{q_a S_b S_d L q_c\} \& F^{(n+1)}$.

But $\text{Inst}\{q_a S_b S_d L q_c\} \& F^{(n+1)} \rightarrow (CC_n \rightarrow CC_{n+1})$

is provable, and so therefore is

$$A(\mathcal{A}) \& F^{(n+1)} \rightarrow (CC_n \rightarrow CC_{n+1})$$

and $(A(\mathcal{M}) \& F^{(n)} \rightarrow CC_n) \rightarrow (A(\mathcal{M}) \& F^{(n+1)} \rightarrow CC_{n+1})$,

i.e. $CF_n \rightarrow CF_{n+1}$.

CF_n is provable for each n . Now it is the assumption of this lemma that S_1 appears somewhere, in some complete configuration, in the sequence of symbols printed by \mathcal{M} ; that is, for some integers N, K , CC_N has $R_{S_1}(u^{(N)}, w^{(K)})$ as one of its terms, and therefore $CC_N \rightarrow R_{S_1}(u^{(N)}, w^{(K)})$ is provable. We have then

$$CC_N \rightarrow R_{S_1}(u^{(N)}, w^{(K)})$$

and $A(\mathcal{M}) \& F^{(N)} \rightarrow CC^N$.

We also have

$$(\exists u) A(\mathcal{M}) \rightarrow (\exists u)(\exists u') \dots (\exists u^{(N')}) (A(\mathcal{M}) \& F^{(N)}),$$

where $N' = \max(N, K)$. And so

$$(\exists u) A(\mathcal{M}) \rightarrow (\exists u)(\exists u') \dots (\exists u^{(N')}) R_{S_1}(u^{(N)}, w^{(K)}),$$

$$(\exists u) A(\mathcal{M}) \rightarrow (\exists u^{(N)})(\exists u^{(K)}) R_{S_1}(u^{(N)}, w^{(K)}),$$

$$(\exists u) A(\mathcal{M}) \rightarrow (\exists s)(\exists t) R_{S_1}(s, t),$$

i.e. $\text{Un}(\mathcal{M})$ is provable.

This completes the proof of Lemma 1.

LEMMA 2. *If $\text{Un}(\mathcal{M})$ is provable, then S_1 appears on the tape in some complete configuration of \mathcal{M} .*

If we substitute any propositional functions for function variables in a provable formula, we obtain a true proposition. In particular, if we substitute the meanings tabulated on pp. 259–260 in $\text{Un}(\mathcal{M})$, we obtain a true proposition with the meaning “ S_1 appears somewhere on the tape in some complete configuration of \mathcal{M} ”.

We are now in a position to show that the Entscheidungsproblem cannot be solved. Let us suppose the contrary. Then there is a general (mechanical) process for determining whether $\text{Un}(\mathcal{M})$ is provable. By Lemmas 1 and 2, this implies that there is a process for determining whether \mathcal{M} ever prints 0, and this is impossible, by § 8. Hence the Entscheidungsproblem cannot be solved.

In view of the large number of particular cases of solutions of the Entscheidungsproblem for formulae with restricted systems of quantors, it

is interesting to express $\text{Un}(\mathcal{M})$ in a form in which all quantors are at the beginning. $\text{Un}(\mathcal{M})$ is, in fact, expressible in the form

$$(u)(\exists x)(w)(\exists u_1) \dots (\exists u_n) \mathfrak{B}, \quad (\text{I})$$

where \mathfrak{B} contains no quantors, and $n = 6$. By unimportant modifications we can obtain a formula, with all essential properties of $\text{Un}(\mathcal{M})$, which is of form (I) with $n = 5$.

Added 28 August, 1936.

APPENDIX.

Computability and effective calculability

The theorem that all effectively calculable (λ -definable) sequences are computable and its converse are proved below in outline. It is assumed that the terms “well-formed formula” (W.F.F.) and “conversion” as used by Church and Kleene are understood. In the second of these proofs the existence of several formulae is assumed without proof; these formulae may be constructed straightforwardly with the help of, *e.g.*, the results of Kleene in “A theory of positive integers in formal logic”, *American Journal of Math.*, 57 (1935), 153–173, 219–244.

The W.F.F. representing an integer n will be denoted by N_n . We shall say that a sequence γ whose n -th figure is $\phi_\gamma(n)$ is λ -definable or effectively calculable if $1 + \phi_\gamma(u)$ is a λ -definable function of n , *i.e.* if there is a W.F.F. M_γ such that, for all integers n ,

$$\{M_\gamma\}(N_n) \text{ conv } N_{\phi_\gamma(n)+1},$$

i.e. $\{M_\gamma\}(N_n)$ is convertible into $\lambda xy.x(x(y))$ or into $\lambda xy.x(y)$ according as the n -th figure of λ is 1 or 0.

To show that every λ -definable sequence γ is computable, we have to show how to construct a machine to compute γ . For use with machines it is convenient to make a trivial modification in the calculus of conversion. This alteration consists in using x, x', x'', \dots as variables instead of a, b, c, \dots . We now construct a machine \mathcal{L} which, when supplied with the formula M_γ , writes down the sequence γ . The construction of \mathcal{L} is somewhat similar to that of the machine \mathcal{J} which proves all provable formulae of the functional calculus. We first construct a choice machine \mathcal{L}_1 , which, if supplied with a W.F.F., M say, and suitably manipulated, obtains any formula into which M is convertible. \mathcal{L}_1 can then be modified so as to yield an automatic machine \mathcal{L}_2 which obtains successively all the formulae

into which M is convertible (cf. foot-note p. 252). The machine \mathcal{L} includes \mathcal{L}_2 as a part. The motion of the machine \mathcal{L} when supplied with the formula M_γ is divided into sections of which the n -th is devoted to finding the n -th figure of γ . The first stage in this n -th section is the formation of $\{M_\gamma\}(N_n)$. This formula is then supplied to the machine \mathcal{L}_2 , which converts it successively into various other formulae. Each formula into which it is convertible eventually appears, and each, as it is found, is compared with

$$\lambda x \left[\lambda x' \left[\{x\}(\{x\}(x')) \right] \right], \text{ i.e. } N_2,$$

and with

$$\lambda x \left[\lambda x' [\{x\}(x')] \right], \text{ i.e. } N_1.$$

If it is identical with the first of these, then the machine prints the figure 1 and the n -th section is finished. If it is identical with the second, then 0 is printed and the section is finished. If it is different from both, then the work of \mathcal{L}_2 is resumed. By hypothesis, $\{M_\gamma\}(N_n)$ is convertible into one of the formulae N_2 or N_1 ; consequently the n -th section will eventually be finished, i.e. the n -th figure of γ will eventually be written down.

To prove that every computable sequence γ is λ -definable, we must show how to find a formula M_γ such that, for all integers n ,

$$\{M_\gamma\}(N_n) \text{ conv } N_{1+\phi_\gamma(n)}.$$

Let \mathcal{M} be a machine which computes γ and let us take some description of the complete configurations of \mathcal{M} by means of numbers, e.g. we may take the D.N. of the complete configuration as described in §6. Let $\xi(n)$ be the D.N. of the n -th complete configuration of \mathcal{M} . The table for the machine \mathcal{M} gives us a relation between $\xi(n+1)$ and $\xi(n)$ of the form

$$\xi(n+1) = \rho_\gamma(\xi(n)),$$

where ρ_γ is a function of very restricted, although not usually very simple, form: it is determined by the table for \mathcal{M} . ρ_γ is λ -definable (I omit the proof of this), i.e. there is a W.F.F. A_γ such that, for all integers n ,

$$\{A_\gamma\}(N_{\xi(n)}) \text{ conv } N_{\xi(n+1)}.$$

Let U stand for

$$\lambda u \left[\{u\}(A_\gamma)(N_r) \right],$$

where $r = \xi(0)$; then, for all integers n ,

$$\{U_\gamma\}(N_n) \text{ conv } N_{\xi(n)}.$$

It may be proved that there is a formula V such that

$$\left\{ \{V\}(N_{\xi(n+1)}) \right\} (N_{\xi(n)}) \begin{cases} \text{conv } N_1 & \text{if, in going from the } n\text{-th to the } (n+1)\text{-th} \\ & \text{complete configuration, the figure 0} \\ & \text{is printed.} \\ \text{conv } N_2 & \text{if the figure 1 is printed.} \\ \text{conv } N_3 & \text{otherwise.} \end{cases}$$

Let W_γ stand for

$$\lambda u \left[\left\{ \{V\} \left(\{A_\gamma\}(\{U_\gamma\}(u)) \right) \right\} (\{U_\gamma\}(u)) \right],$$

so that, for each integer n ,

$$\left\{ \{V\}(N_{\xi(n+1)}) \right\} (N_{\xi(n)}) \text{ conv } \{W_\gamma\}(N_n),$$

and let Q be a formula such that

$$\left\{ \{Q\}(W_\gamma) \right\} (N_s) \text{ conv } N_{r(s)},$$

where $r(s)$ is the s -th integer q for which $\{W_\gamma\}(N_q)$ is convertible into either N_1 or N_2 . Then, if M_γ stands for

$$\lambda w \left[\{W_\gamma\} \left(\left\{ \{Q\}(W_\gamma) \right\} (w) \right) \right],$$

it will have the required property†.

The Graduate College,
Princeton University,
New Jersey, U.S.A.

† In a complete proof of the λ -definability of computable sequences it would be best to modify this method by replacing the numerical description of the complete configurations by a description which can be handled more easily with our apparatus. Let us choose certain integers to represent the symbols and the m -configurations of the machine. Suppose that in a certain complete configuration the numbers representing the successive symbols on the tape are $s_1 s_2 \dots s_n$, that the m -th symbol is scanned, and that the m -configuration has the number t ; then we may represent this complete configuration by the formula

$$[N_{s_1}, N_{s_2}, \dots, N_{s_{m-1}}, [N_t, N_{s_m}], [N_{s_{m+1}}, \dots, N_{s_n}],$$

where

$$[a, b] \text{ stands for } \lambda u \left[\{u\}(a)(b) \right],$$

$$[a, b, c] \text{ stands for } \lambda u \left[\left\{ \{u\}(a)(b) \right\} (c) \right],$$

etc.

Alan Turing, at age 35, about the time he wrote "Intelligent Machinery"

Alan Turing's Forgotten Ideas in Computer Science

Well known for the machine, test and thesis that bear his name, the British genius also anticipated neural-network computers and "hypercomputation"

by B. Jack Copeland and Diane Proudfoot

Alan Mathison Turing conceived of the modern computer in 1935. Today all digital computers are, in essence, "Turing machines." The British mathematician also pioneered the field of artificial intelligence, or AI, proposing the famous and widely debated Turing test as a way of determining whether a suitably programmed computer can think. During World War II, Turing was instrumental in breaking the German Enigma code in part of a top-secret British operation that historians say shortened the war in Europe by two years. When he died at the age of 41, Turing was doing the earliest work on what would now be called artificial life, simulating the chemistry of biological growth.

Throughout his remarkable career, Turing had no great interest in publicizing his ideas. Consequently, important aspects of his work have been neglected or forgotten over the years. In particular, few people—even those knowledgeable about computer science—are familiar with Turing's fascinating anticipation of connectionism, or neuronlike computing. Also neglected are his groundbreaking theoretical concepts in the exciting area of "hypercomputation." According to some experts, hypercomputers might one day solve problems heretofore deemed intractable.

The Turing Connection

Digital computers are superb number crunchers. Ask them to predict a rocket's trajectory or calculate the financial figures for a large multinational corporation, and they can churn out the answers in seconds. But seemingly simple actions that people routinely perform, such as recognizing a face or reading handwriting, have been devilishly tricky to program. Perhaps the networks of neurons that make up the brain have a natural facility for such tasks that standard computers lack. Scientists have thus been investigating computers modeled more closely on the human brain.

Connectionism is the emerging science of computing with networks of artificial neurons. Currently researchers usually simulate the neurons and their interconnections within an ordinary digital computer (just as engineers create virtual models of aircraft wings and skyscrapers). A training algorithm that runs on the computer adjusts the connections between the neurons, honing the network into a special-purpose machine dedicated to some particular function, such as forecasting international currency markets.

Modern connectionists look back to Frank Rosenblatt, who published the first of many papers on the topic in 1957, as the founder of their approach. Few realize that Turing had already investigated connectionist networks as early as 1948, in a little-known paper entitled "Intelligent Machinery."

Written while Turing was working for the National Physical Laboratory in London, the manuscript did not meet with his employer's approval. Sir Charles Darwin, the rather headmasterly director of the laboratory and grandson of the great English naturalist, dismissed it as a "schoolboy essay." In reality, this farsighted paper was the first manifesto of the field of artificial intelli-

gence. In the work—which remained unpublished until 1968, 14 years after Turing's death—the British mathematician not only set out the fundamentals of connectionism but also brilliantly introduced many of the concepts that were later to become central to AI, in some cases after reinvention by others.

In the paper, Turing invented a kind of neural network that he called a "B-type

be accomplished by groups of NAND neurons. Furthermore, he showed that even the connection modifiers themselves can be built out of NAND neurons. Thus, Turing specified a network made up of nothing more than NAND neurons and their connecting fibers—about the simplest possible model of the cortex.

In 1958 Rosenblatt defined the theoretical basis of connectionism in one succinct statement: "Stored information takes the form of new connections, or transmission channels in the nervous system (or the creation of conditions which are functionally equivalent to new connections.)" Because the destruction of existing connections can be functionally equivalent to the creation of new ones, researchers can build a network for accomplishing a specific task by taking one with an excess of connections and selectively destroying some of them. Both actions—destruction and creation—are employed in the training of Turing's B-types.

At the outset, B-types contain random interneuronal connections whose modifiers have been set by chance to either pass or interrupt. During training, unwanted connections are destroyed by switching their attached modifiers to interrupt mode. Conversely, changing a modifier from interrupt to pass in effect creates a connection. This selective culling and enlivening of connections hones the initially random network into one organized for a given job.

Once set, a modifier will maintain its function (either "pass" or "interrupt") unless it receives a pulse on the other training fiber. The presence of these ingenious connection modifiers enables the training of a B-type unorganized machine by means of what Turing called "appropriate interference, mimicking education." Actually, Turing theorized that "the cortex of an infant is an unorganized machine, which can be organized by suitable interfering training."

Each of Turing's model neurons has two input fibers, and the output of a neuron is a simple logical function of its two inputs. Every neuron in the network executes the same logical operation of "not and" (or NAND): the output is 1 if either of the inputs is 1. If both inputs are 1, then the output is 0.

Turing selected NAND because every other logical (or Boolean) operation can

Turing wished to investigate other kinds of unorganized machines, and he longed to simulate a neural network and its training regimen using an ordinary digital computer. He would, he said, "allow the whole system to run for an appreciable period, and then break in as a kind of 'inspector of schools' and see what progress had been made." But his own work on neural networks was carried out shortly before the first general-purpose electronic computers became available. (It was not until 1954, the year of Turing's death, that Belmont G. Farley and Wesley A. Clark succeeded at the Massachusetts Institute of Technology in running the first computer simulation of a small neural network.)

Paper and pencil were enough, though, for Turing to show that a sufficiently large B-type neural network can be configured (via its connection modifiers)

in such a way that it becomes a general-purpose computer. This discovery illuminates one of the most fundamental problems concerning human cognition.

From a top-down perspective, cognition includes complex sequential processes, often involving language or other forms of symbolic representation, as in mathematical calculation. Yet from a bottom-up view, cognition is nothing but the simple firings of neurons. Cognitive scientists face the problem of how to reconcile these very different perspectives.

Turing's discovery offers a possible solution: the cortex, by virtue of being a neural network acting as a general-purpose computer, is able to carry out the sequential, symbol-rich processing discerned in the view from the top. In 1948 this hypothesis was well ahead of its time, and today it remains among the best guesses concerning one of cognitive science's hardest problems.

Computing the Uncomputable

In 1935 Turing thought up the abstract device that has since become known as the "universal Turing machine." It consists of a limitless memory

that stores both program and data and a scanner that moves back and forth through the memory, symbol by symbol, reading the information and writing additional symbols. Each of the machine's basic actions is very simple—such as "identify the symbol on which the scanner is positioned," "write '1'" and "move one position to the left." Complexity is achieved by chaining together large numbers of these basic actions. Despite its simplicity, a universal Turing machine can execute any task that can be done by the most powerful of today's computers. In fact, all modern digital computers are in essence universal Turing machines [see "Turing Machines," by John E. Hopcroft; SCIENTIFIC AMERICAN, May 1984].

Turing's aim in 1935 was to devise a machine—one as simple as possible—capable of any calculation that a human mathematician working in accordance with some algorithmic method could perform, given unlimited time, energy, paper and pencils, and perfect concentration. Calling a machine "universal" merely signifies that it is capable of all such calculations. As Turing himself wrote, "Electronic computers are in-

tended to carry out any definite rule-of-thumb process which could have been done by a human operator working in a disciplined but unintelligent manner."

Such powerful computing devices notwithstanding, an intriguing question arises: Can machines be devised that are capable of accomplishing even more? The answer is that these "hypermachines" can be described on paper, but no one as yet knows whether it will be possible to build one. The field of hypercomputation is currently attracting a growing number of scientists. Some speculate that the human brain itself—the most complex information processor known—is actually a naturally occurring example of a hypercomputer.

Before the recent surge of interest in hypercomputation, any information-processing job that was known to be too difficult for universal Turing machines was written off as "uncomputable." In this sense, a hypermachine computes the uncomputable.

Examples of such tasks can be found in even the most straightforward areas of mathematics. For instance, given arithmetical statements picked at random, a universal Turing machine may

not always be able to tell which are theorems (such as " $7 + 5 = 12$ ") and which are nontheorems (such as "every number is the sum of two even numbers").

Another type of uncomputable problem comes from geometry. A set of tiles—variously sized squares with different colored edges—"tiles the plane" if the Euclidean plane can be covered by copies of the tiles with no gaps or overlaps and with adjacent edges always the same color. Logicians William Hanf and Dale Myers of the University of Hawaii have discovered a tile set that tiles the plane only in patterns too complicated for a universal Turing machine to calculate. In the field of computer science, a universal Turing machine cannot always predict whether a given program will terminate or continue running forever. This is sometimes expressed by saying that no general-purpose programming language (Pascal, BASIC, Prolog, C and so on) can have a foolproof crash debugger: a tool that detects all bugs that could lead to crashes, including errors that result in infinite processing loops.

Turing himself was the first to investigate the idea of machines that can perform mathematical tasks too difficult

Few realize that Turing had already investigated connectionist networks as early as 1948.

Turing's Anticipation of Connectionism

In a paper that went unpublished until 14 years after his death (top), Alan Turing described a network of artificial neurons connected in a random manner. In this "B-type unorganized machine" (bottom left), each connection passes through a modifier that is set either to allow data to pass unchanged (green fiber) or to destroy the transmitted information (red fiber). Switching the modifiers from one mode to the other enables the network to be trained. Note that each neuron has two inputs (bottom left, inset) and executes the simple logical operation of "not and," or NAND: if both inputs are 1, then the output is 0; otherwise the output is 1.

In Turing's network the neurons interconnect freely. In contrast, modern networks (bottom center) restrict the flow of information from layer to layer of neurons. Connectionists aim to simulate the neural networks of the brain (bottom right).

TOM MOORE (ILLUSTRATIONS); COLLEGE MODERN ARCHIVES; CAMBRIDGE UNIVERSITY LIBRARY (TOP); PETER ARNOLD, INC. (BOTTOM RIGHT)

Using an Oracle to Compute the Uncomputable

Alan Turing proved that his universal machine—and by extension, even today's most powerful computers—could never solve certain problems. For instance, a universal Turing machine cannot always determine whether a given software program will terminate or continue running forever. In some cases, the best the universal machine can do is execute the program and wait—maybe eternally—for it to finish. But in his doctoral thesis (*below*), Turing did imagine that a machine equipped with a special “oracle” could perform this and other “uncomputable” tasks. Here is one example of how, in principle, an oracle might work.

Consider a hypothetical machine for solving the formidable

EXCERPT FROM TURING'S THESIS

Let us suppose that we are supplied with some unspecified means of solving number theoretic problems; a kind of oracle as it were. We will not go any further into the nature of this oracle than to say that it cannot be a machine. With the help of the oracle we could form a new kind of machine (call them *o-machines*), having as one of its fundamental processes that of solving a given number theoretic problem. More definitely these machines are to

COMPUTER PROGRAM

“terminating program” problem (*above*). A computer program can be represented as a finite string of 1s and 0s. This sequence of digits can also be thought of as the binary representation of an integer, just as 1011011 is the equivalent of 91. The oracle's job can then be restated as, “Given an integer that represents a program (for any computer that can be simulated by a universal Turing machine), output a ‘1’ if the program will terminate or a ‘0’ otherwise.”

The oracle consists of a perfect measuring device and a store, or memory, that contains a precise value—call it τ for Turing—of some physical quantity. (The memory might, for example, resemble a capacitor storing an exact amount of

electricity.) The value of τ is an irrational number; its written representation would be an infinite string of binary digits, such as 0.00000001101...

The crucial property of τ is that its individual digits happen to represent accurately which programs terminate and which do not. So, for instance, if the integer representing a program were 8,735,439, then the oracle could by measurement obtain the 8,735,439th digit of τ (counting from left to right after the decimal point). If that digit were 0, the oracle would conclude that the program will process forever.

Obviously, without τ the oracle would be useless, and finding some physical variable in nature that takes this exact value might very well be impossible. So the search is on for some practicable way of implementing an oracle. If such a means were found, the impact on the field of computer science could be enormous. —B.J.C. and D.P.

for universal Turing machines. In his 1938 doctoral thesis at Princeton University, he described “a new kind of machine,” the “O-machine.”

An O-machine is the result of augmenting a universal Turing machine with a black box, or “oracle,” that is a mechanism for carrying out uncomputable tasks. In other respects, O-machines are similar to ordinary computers. A digitally encoded program is

chined—for example, “identify the symbol in the scanner”—might take place.) But notional mechanisms that fulfill the specifications of an O-machine's black box are not difficult to imagine [*see box above*]. In principle, even a suitable B-type network can compute the uncomputable, provided the activity of the neurons is desynchronized. (When a central clock keeps the neurons in step with one another, the functioning of the network can be exactly simulated by a universal Turing machine.)

In the exotic mathematical theory of hypercomputation, tasks such as that of distinguishing theorems from nontheorems in arithmetic are no longer uncomputable. Even a debugger that can tell whether any program written in C, for example, will enter an infinite loop is theoretically possible.

If hypercomputers can be built—and that is a big if—the potential for cracking logical and mathematical problems hitherto deemed intractable will be enormous. Indeed, computer science may be approaching one of its most significant advances since researchers

wired together the first electronic embodiment of a universal Turing machine decades ago. On the other hand, work on hypercomputers may simply fizzle out for want of some way of realizing an oracle.

The search for suitable physical, chemical or biological phenomena is getting under way. Perhaps the answer will be complex molecules or other structures that link together in patterns as complicated as those discovered by Hanf and Myers. Or, as suggested by Jon Doyle of M.I.T., there may be naturally occurring equilibrating systems with discrete spectra that can be seen as carrying out, in principle, an uncomputable task, producing appropriate output (1 or 0, for example) after being bombarded with input.

Outside the confines of mathematical logic, Turing's O-machines have largely been forgotten, and instead a myth has taken hold. According to this apocryphal account, Turing demonstrated in the mid-1930s that hypermachines are impossible. He and Alonzo Church, the logician who was Turing's doctoral adviser at Princeton, are mistakenly credited with having enunciated a principle to the effect that a universal Turing machine can exactly simulate the behavior

of any other information-processing machine. This proposition, widely but incorrectly known as the Church-Turing thesis, implies that no machine can carry out an information-processing task that lies beyond the scope of a universal Turing machine. In truth, Church and Turing claimed only that a universal Turing machine can match the behavior of any human mathematician working with paper and pencil in accordance with an algorithmic method—a considerably

weaker claim that certainly does not rule out the possibility of hypermachines.

Even among those who are pursuing the goal of building hypercomputers, Turing's pioneering theoretical contributions have been overlooked. Experts routinely talk of carrying out information processing “beyond the Turing limit” and describe themselves as attempting to “break the Turing barrier.” A recent review in *New Scientist* of this emerging field states that the new ma-

chines “fall outside Turing's conception” and are “computers of a type never envisioned by Turing,” as if the British genius had not conceived of such devices more than half a century ago. Sadly, it appears that what has already occurred with respect to Turing's ideas on connectionism is starting to happen all over again.

The Final Years

In the early 1950s, during the last years of his life, Turing pioneered the field of artificial life. He was trying to simulate a chemical mechanism by which the genes of a fertilized egg cell may determine the anatomical structure of the resulting animal or plant. He described this research as “not altogether unconnected” to his study of neural networks, because “brain structure has to be... achieved by the genetical embryological mechanism, and this theory that I am now working on may make clearer what restrictions this really implies.” During this period, Turing achieved the distinction of being the first to engage in the computer-assisted exploration of nonlinear dynamical systems. His theory used nonlinear differential equations to express the chemistry of growth.

But in the middle of this groundbreaking investigation, Turing died from cyanide poisoning, possibly by his own hand. On June 8, 1954, shortly before what would have been his 42nd birthday, he was found dead in his bedroom. He had left a large pile of handwritten notes and some computer programs. Decades later this fascinating material is still not fully understood.

Even among experts, Turing's pioneering theoretical concept of a hypermachine has largely been forgotten.

fed in, and the machine produces digital output from the input using a step-by-step procedure of repeated applications of the machine's basic operations, one of which is to pass data to the oracle and register its response.

Turing gave no indication of how an oracle might work. (Neither did he explain in his earlier research how the basic actions of a universal Turing ma-

The Authors

B. JACK COPELAND and DIANE PROUDFOOT are the directors of the Turing Project at the University of Canterbury, New Zealand, which aims to develop and apply Turing's ideas using modern techniques. The authors are professors in the philosophy department at Canterbury, and Copeland is visiting professor of computer science at the University of Portsmouth in England. They have written numerous articles on Turing. Copeland's *Turing's Machines and The Essential Turing* are forthcoming from Oxford University Press, and his *Artificial Intelligence* was published by Blackwell in 1993. In addition to the logical study of hypermachines and the simulation of B-type neural networks, the authors are investigating the computer models of biological growth that Turing was working on at the time of his death. They are organizing a conference in London in May 2000 to celebrate the 50th anniversary of the pilot model of the Automatic Computing Engine, an electronic computer designed primarily by Turing.

	1	2	3	4	5	6	7	8	...

\Rightarrow set of algorithms is countable!

Theorem [Turing]: the set of functions is not countable.

Theorem: Boolean functions $\{f | f: \mathbb{N} \rightarrow \{0,1\}\}$ are uncountable.

Proof: Assume Boolean functions were countable; i.e.,
 \exists table containing all of f_i 's and their corresponding values:

f_i	$f_i(1)$	$f_i(2)$	$f_i(3)$	$f_i(4)$	$f_i(5)$	$f_i(6)$	$f_i(7)$	$f_i(8)$	$f_i(9)$	
f_1	0	0	0	0	0	0	0	0	0	...
f_2	1	1	1	1	1	1	1	1	1	...
f_3	0	1	0	1	0	1	0	1	0	...
f_4	1	1	0	1	0	0	0	1	0	...
f_5	0	1	1	0	1	0	1	0	0	...
...
$f'(i) =$	1	0	1	0	0	...				$f': \mathbb{N} \rightarrow \{0,1\}$

Diagonalization proof
Real numbers!

But f' is missing from our table! $f' \neq f_k \forall k \in \mathbb{N}$
 \Rightarrow table is not a 1-1 correspondence between \mathbb{N} and f_i 's
 \Rightarrow contradiction $\Rightarrow \{f | f: \mathbb{N} \rightarrow \{0,1\}\}$ is not countable!
 \Rightarrow There are more Boolean functions than natural numbers!

Theorem: the set of algorithms is countable.

Theorem: the set of functions is uncountable.

Theorem: the Boolean functions are uncountable.

1 ↔ “main(){}”
⋮
9372 ↔ “main(int n; n=13;)”

$f'(i) = 1 \ 0 \ 1 \ 0 \ 0 \ \dots$ $f': \mathbb{N} \rightarrow \{0,1\}$

Diagonalization

Non-existence proof

Corollary: there are “more” functions than algorithms / programs.

Corollary: some functions are not computable by any algorithm!

Corollary: most functions are not computable by any algorithm!

Corollary: there are “more” Boolean functions than algorithms.

Corollary: some Boolean functions on \mathbb{N} are not computable.

Corollary: most Boolean functions on \mathbb{N} are not computable.

Theorem: most **Boolean** functions on \mathbb{N} are not computable.

Q: Can we find a concrete example of an uncomputable function?

A [Turing]: Yes, for example, the **Halting** Problem.

Definition: The **Halting** problem: given a program P and input I, will P **halt** if we ran it on I?

Define $H: \mathbb{N} \times \mathbb{N} \rightarrow \{0, 1\}$

$H(P, I) = 1$ if TM P **halts** on input I

$H(P, I) = 0$ otherwise

Notes:

- P and I can be encoded as integers, in some **canonical order**.
- **H** is an **everywhere-defined Boolean** function on natural pairs.
- Alternatively, both P and I can be **encoded** as strings in Σ^* .
- We can modify **H** to take only a **single** input: $H'(2^P 3^I)$ or $H'(P\$I)$

Why $2^P 3^I$? ← Gödel numbering / encoding
 What else will work?

Theorem [Turing]: the halting problem (**H**) is not computable.

Corollary: we can not algorithmically detect all infinite loops.

Q: Why not? E.g., do the following programs halt?

```
main()
{ int k=3; }
```

Halts!

```
main()
{ while(1) {} }
```

Runs forever!

```
main()
{ Find a Fermat
triple  $a^n+b^n=c^n$ 
with  $n>2$  then stop }
```

Runs forever!

Open from 1637-1995!

```
main()
{ Find a Goldbach
integer that is not a sum
of two primes & stop }
```

?

Still open since 1742!

Theorem: solving the halting problem is at least as hard as solving arbitrary **open mathematical problems!**

Corollary: Its not about size!

THE WOLFRAM 2,3 TURING MACHINE RESEARCH PRIZE

Oct 24, 2007

We have the solution!
Wolfram's 2,3 Turing machine
is universal

Congratulations Alex Smith.

[FAQs »](#)

*A universal Turing machine is powerful enough to emulate any standard computer.
The question is: how simple can the rules for a universal Turing machine be?*

*Since the 1960s it has been known that there is a universal 7,4 machine. In *A New Kind of Science*, Stephen Wolfram found a universal 2,5 machine, and suggested that the particular 2,3 machine that is the subject of this prize might be universal.*

The prize is for determining whether or not the 2,3 machine is in fact universal.

Wolfram's 2,3 Turing machine **is** universal!

The lower limit on Turing machine universality is proved—
providing new evidence for Wolfram's Principle of Computational Equivalence.

The Wolfram 2,3 Turing Machine Research Prize has been won by 20-year-old **Alex Smith** of Birmingham, UK.

The Rules for the Machine

The rules for the Turing machine that is the subject of this prize are:

$\{\{1, 2\} \rightarrow \{1, 1, -1\}, \{1, 1\} \rightarrow \{1, 2, -1\}, \{1, 0\} \rightarrow \{2, 1, 1\},$
 $\{2, 2\} \rightarrow \{1, 0, 1\}, \{2, 1\} \rightarrow \{2, 2, 1\}, \{2, 0\} \rightarrow \{1, 2, -1\}\}$

where this means {state, color} \rightarrow {state, color, offset}. (Colors of cells on the tape are sometimes instead thought of as "symbols" written to the tape.)

These rules can be represented pictorially by:

where the orientation of each arrow represents the state.

The rules can also be represented by the state transition diagram:

**A 2-state 3-symbol
universal Turing machine!
(the smallest possible)**

In Wolfram's numbering scheme for Turing machines, this is machine 596440. There are a total of $(2 \cdot 3 \cdot 2)^2 \cdot 3 = 12^2 \cdot 3 = 2985984$ machines with 2 states and 3 colors.

Note that there is no halt state for this Turing machine.

Theorem [Turing]: the halting problem (**H**) is not computable.

Ex: the “ $3X+1$ ” problem (the Ulam conjecture):

- Start with any integer $X > 0$
- If X is even, then replace it with $X/2$
- If X is odd then replace it with $3X+1$
- Repeat until $X=1$ (i.e., short cycle 4, 2, 1, ...)

Ex: **26 terminates** after 10 steps

27 terminates after 111 steps

Termination verified for $X < 10^{18}$

Q: Does this **terminate** for every $X > 0$?

A: **Open since 1937!**

“Mathematics is not yet ready for such confusing, troubling, and hard problems.” - Paul Erdős, who offered a \$500 bounty for a solution to this problem

Observation: **termination** is in general **difficult to detect!**

Theorem [Turing]: the **halting** problem (**H**) is not computable.

Proof: Assume \exists algorithm **S** that solves the **halting** problem **H**, that always **stops** with the **correct** answer for any **P** & **I**.

Non-existence proof!

Using **S**, construct algorithm / TM **T**:

$T(T)$ halts $\Rightarrow T(T)$ does not halt
 $T(T)$ does not halt $\Rightarrow T(T)$ halts } $Q \Leftrightarrow \sim Q \Rightarrow$ Contradiction!
 $\Rightarrow S$ cannot exist! (at least as an algorithm / program / TM)

Q: When do we want to feed a program to **itself** in **practice**?

A: When we build **compilers**.

Q: Why?

A: To make them more **efficient**!

To **boot-strap** the coding in the compiler's own language!

Theorem: Infinite loop detection is not computable.

OPERATION: DUCKLING LOOP

Theorem: virus detection is not computable.

I'VE GOT A BUNCH OF VIRTUAL WINDOWS MACHINES NETWORKED TOGETHER, HOOKED UP TO AN INCOMING PIPE FROM THE NET. THEY EXECUTE EMAIL ATTACHMENTS, SHARE FILES, AND HAVE NO SECURITY PATCHES.

BETWEEN THEM THEY HAVE PRACTICALLY EVERY VIRUS..

THERE ARE MAILTROJANS, WARHOL WORMS, AND ALL SORTS OF EXOTIC POLYMORPHICS. A MONITORING SYSTEM ADDS AND WIPES MACHINES AT RANDOM. THE DISPLAY SHOWS THE VIRUSES AS THEY MOVE THROUGH THE NETWORK,

GROWING AND STRUGGLING.

YOU KNOW, NORMAL PEOPLE JUST HAVE AQUARIUMS.

GOOD MORNING, BLASTER. ARE YOU AND W32.WELCHIA GETTING ALONG?

WHO'S A GOOD VIRUS? YOU ARE! YES, YOU ARE!

One of My Favorite Turing Machines

Apple iPad (2015):

- < 1/4" thin
- < 1 pound weight
- 2048 x 1536 (326 ppi res)
multi-touch screen
- 128 GB memory
- 1.5 MHz 64-bit 3-core A8X
- 8 MP camera & HD video
- WiFi, cellular, GPS
- Compass, barometer
- battery life 10 hours

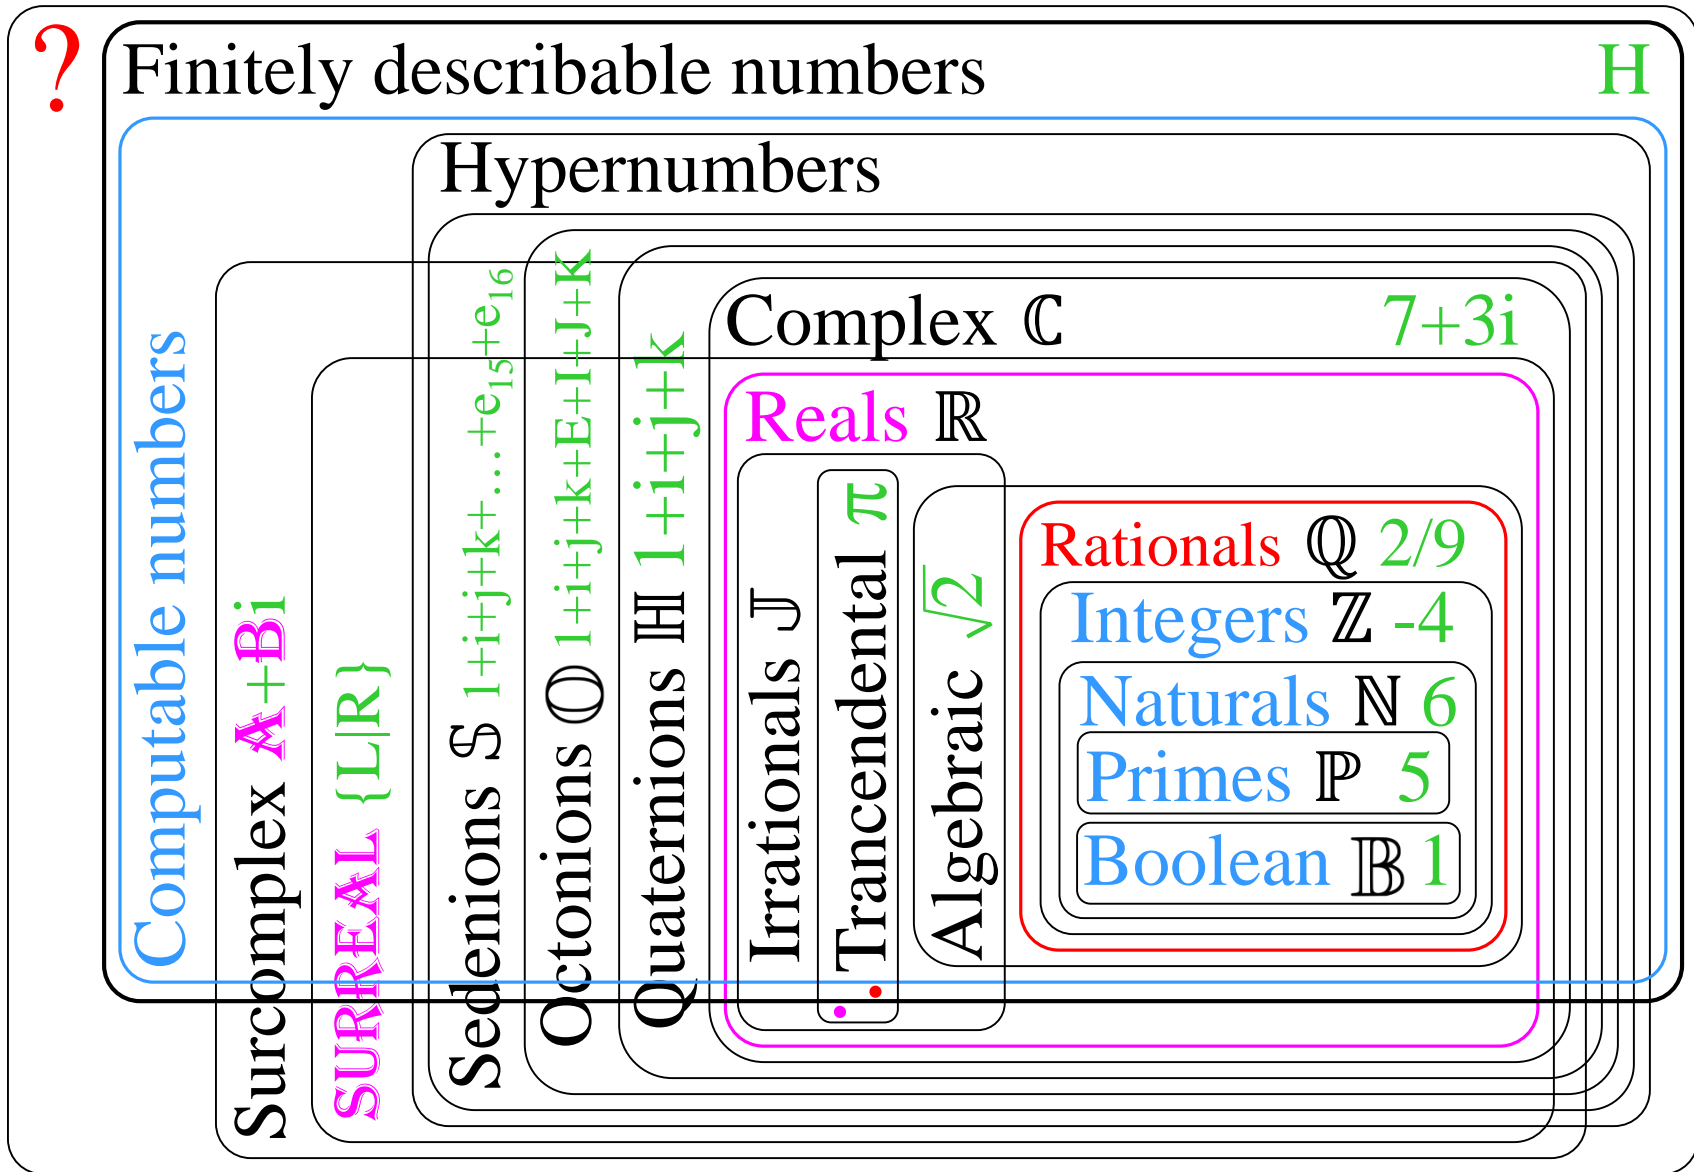

Another Great Touring Machine

Tesla Model S (2013):

- EV with **300** mi range
- 0-60 in **2.8** seconds!
- **Auto-pilot!** (hands free)
- **Safest** car ever tested
- Big “**iPad**” dash
- Internet **software updates**

Generalized Numbers

Theorem: some real numbers are not finitely describable!

Theorem: some finitely describable real numbers are not computable!

Theorem: Some **real numbers** are not **finitely describable**.

Proof: The number of **finite descriptions** is **countable**.

The number of **real numbers** is **not countable**.

⇒ **Most** **real numbers** do not have **finite descriptions**.

1 ↔ "main0{}"
 ⋮
 9372 ↔ "main{int n; n=13;}"
 ⋮
 10^{100} ↔ "<UNIX>"
 ⋮
 10^{999} ↔ "<Windows Vista>"
 ⋮
 $10^{10^{100}}$ ↔ "<super intelligent program>"

Diagonalization!
Canonical order

f_i	$f_i(1)$	$f_i(2)$	$f_i(3)$	$f_i(4)$	$f_i(5)$	$f_i(6)$	$f_i(7)$	$f_i(8)$	$f_i(9)$	
f_1	0	0	0	0	0	0	0	0	0	...
f_2	1	1	1	1	1	1	1	1	1	...
f_3	0	1	0	0	1	0	1	0	0	...
f_4	1	1	0	1	0	0	1	1	0	...
f_5	0	1	1	0	1	1	0	0	0	...
...

$f'(i) = 1 \ 0 \ 1 \ 0 \ 0 \ \dots \ f': \mathbb{N} \rightarrow \{0,1\}$

Diagonalization
Non-existence proof!

Gödel numbering / encoding

Theorem: Some **finitely describable** reals are not **computable**.

Proof: Let $h=0.H_1H_2H_3H_4\dots$ where $H_i=1$ if $i=2^P3^I$ for some integers P & I , and TM P **halts** on input I , and $H_i=0$ otherwise. Clearly $0 < h < 1$ is a **real number** and is **finitely describable**.

If h was computable, then we could exploit an algorithm that computes it into solving the halting problem, a **contradiction**.

⇒ h is not computable.

Reduction / transformation!

Theorem: all computable numbers are **finitely describable**.

Proof: A computable number can be outputted by a TM.

A TM is a (unique) **finite description**.

What the **unsolvability** of the Halting Problem means:

There is no **single** algorithm / program / TM that **correctly** solves **all** instances of the halting problem in **finite** time each.

This result does not necessarily apply if we allow:

- **Incorrectness** on some instances
- **Infinitely large** algorithm / program
- **Infinite number** of finite algorithms / programs
- Some instances to **not be solved**
- **Infinite** “running time” / steps
- Powerful enough **oracles**

Oracles

- Originated in Turing's Ph.D. thesis
 - Named after the “Oracle of Apollo” at Delphi, ancient Greece →
 - Black-box subroutine / language
 - Can compute arbitrary functions
 - Instant computations “for free”
 - Can greatly increase computation power of basic TMs
- E.g., oracle for halting problem

The “Oracle of Omaha”

The “Oracle” of the Matrix

Turing Machines with Oracles

- A special case of “**hyper-computation**”
- Allows “**what if**” analysis: assumes certain undecidable languages can be recognized
- An oracle can profoundly impact the decidability & tractability of a language
- Any language / problem can be “**relativized**” WRT an arbitrary oracle
- Undecidability / **intractability** exists even for oracle machines!

Theorem [Turing]: Some problems are still not computable, even by Turing machines with an oracle for the halting problem!

Theorem [Turing]: the **halting** problem (H^*) is not computable.

Proof: Assume \exists algorithm S^* that solves the **halting** problem H^* , that always **stops** with the **correct** answer for any P^* & I .

Add to P an **H-oracle**:

P^* is "relativized" P .
 S^* is "relativized" S .
 T^* is "relativized" T .

Using S , construct algorithm / TM T^* :

The halting problem for TMs with an **H-oracle** is not computable by TM's with an **H-oracle**!

$T^*(T^*)$ halts $\Rightarrow T^*(T^*)$ does not halt
 $T^*(T^*)$ does not halt $\Rightarrow T^*(T^*)$ halts
 }
 $Q \Leftrightarrow \sim Q \Rightarrow$ Contradiction!

$\Rightarrow S^*$ cannot exist! (at least as an algorithm / program / TM)

Turing Degrees

Alan Turing
1912-1954

Emil Post
1897-1954

Stephen Kleene
1909-1994

- Turing (1937); studied by Post (1944) and Kleene (1954)
- **Quantifies** the non-computability (i.e., algorithmic unsolvability) of (decision) problems and languages
- Some problems are “**more unsolvable**” than others!

Georg Cantor
1845-1918

Diagonalization

- Defines computation “**relative**” to an oracle.
- “**Relativized** computation” - an **infinite hierarchy**!
- A “**relativity theory** of computation”!

Turing degree 1

Turing degree 0

Turing degree 2

Turing Degrees

- **Turing degree** of a set X is the set of all **Turing-equivalent** (i.e., mutually-reducible) sets: an **equivalence class** $[X]$
- Turing degrees form a **partial order** / **join-semilattice**
- $[0]$: the unique Turing degree containing all computable sets
- For set X , the “**Turing jump**” operator X' is the set of indices of oracle TMs which halt when using X as an oracle
- $[0']$: Turing degree of the halting problem H ; $[0'']$: Turing degree of the halting problem H^* for TMs with oracle H .

Alan Turing
1912-1954

Emil Post
1897-1954

Stephen Kleene
1909-1994

Turing Degrees

Alan Turing
1912-1954

Emil Post
1897-1954

Stephen Kleene
1909-1994

- Each Turing degree is **countably infinite** (has exactly \aleph_0 sets)
- There are **uncountably** many (2^{\aleph_0}) Turing degrees
- A Turing degree X is **strictly smaller** than its **Turing jump** X'
- For a Turing degree X , the set of degrees smaller than X is **countable**; set of degrees larger than X is **uncountable** (2^{\aleph_0})
- For every Turing degree X there is an **incomparable** degree (i.e., neither $X \geq Y$ nor $Y \geq X$ holds).
- There are 2^{\aleph_0} pairwise **incomparable** Turing degrees
- For every degree X , there is a degree D **strictly between** X and X' so that $X < D < X'$ (there are actually \aleph_0 of them)

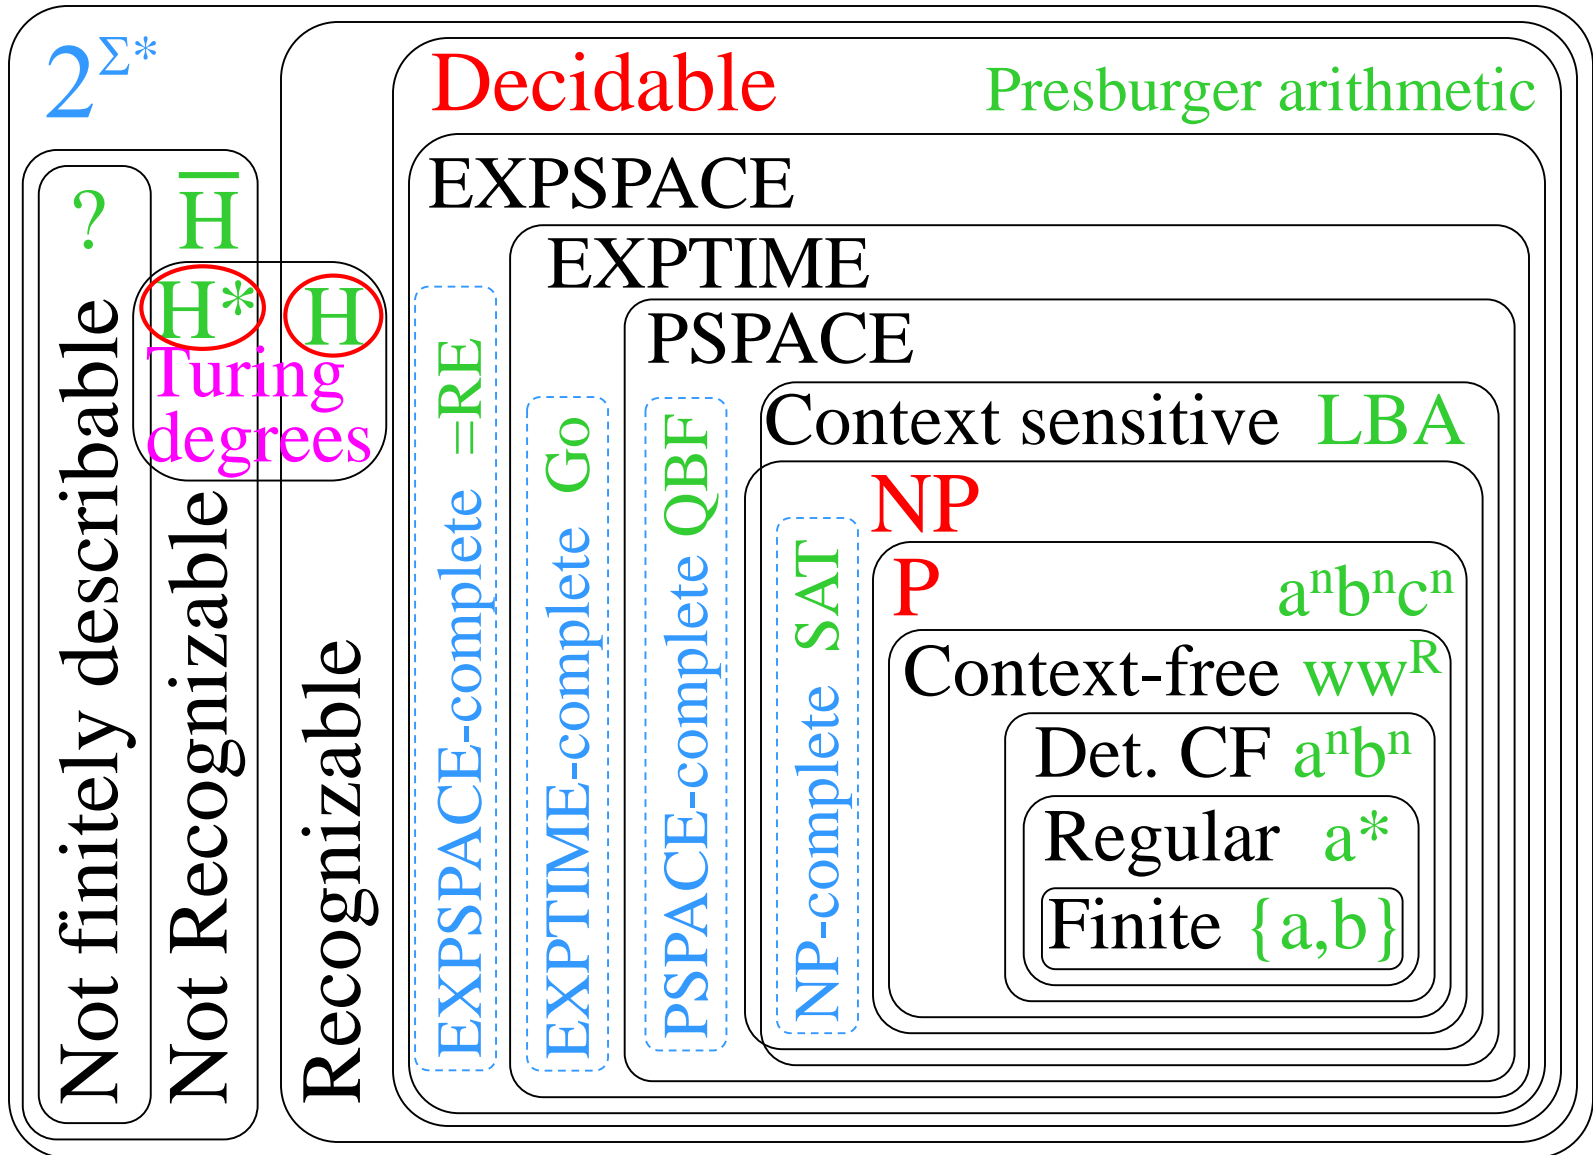

The structure of the **Turing degrees semilattice** is extremely complex!

"THE BEAUTY OF THIS IS THAT IT IS ONLY OF THEORETICAL IMPORTANCE, AND THERE IS NO WAY IT CAN BE OF ANY PRACTICAL USE WHATSOEVER."

The Extended Chomsky Hierarchy

Ideas on complexity and randomness originally suggested by Gottfried W. Leibniz in 1686, combined with modern information theory, imply that there can never be a “theory of everything” for all of mathematics

By Gregory Chaitin

The Limits of Reason

In 1956 *Scientific American* published an article by Ernest Nagel and James R. Newman entitled “Gödel’s Proof.” Two years later the writers published a book with the same title—a wonderful work that is still in print. I was a child, not even a teenager, and I was obsessed by this little book. I remember the thrill of discovering it in the New York Public Library. I used to carry it around with me and try to explain it to other children.

It fascinated me because Kurt Gödel used mathematics to show that mathematics itself has limitations. Gödel refuted the position of David Hilbert, who about a century ago declared that there was a theory of everything for math, a finite set of principles from which one could mindlessly deduce all mathematical truths by tediously following the rules of symbolic logic. But Gödel demonstrated that mathematics contains true statements that cannot be proved that way. His result is based on two self-referential paradoxes: “This statement is false” and “This statement is unprovable.” (For more on Gödel’s incompleteness theorem, see www.sciam.com/ontheweb)

My attempt to understand Gödel’s proof took over my life, and now half a century later I have published a little book of my own.

In some respects, it is my own version of Nagel and Newman’s book, but it does not focus on Gödel’s proof. The only things the two books have in common are their small size and their goal of critiquing mathematical methods.

Unlike Gödel’s approach, mine is based on measuring information and showing that some mathematical facts cannot be compressed into a theory because they are too complicated. This new approach suggests that what Gödel

EXISTENCE OF Ω (Ω)—a specific, well-defined number that cannot be calculated by any computer program—smashes hopes for a complete, all-encompassing mathematics in which every true fact is true for a reason.

PHYSICS: THEORY → CALCULATIONS → PREDICTIONS FOR OBSERVATIONS

MATHEMATICS: AXIOMS → REASONING → THEOREMS

COMPUTING: PROGRAM → EXECUTION ON COMPUTER → OUTPUT

PHYSICS AND MATHEMATICS are in many ways similar to the execution of a program on a computer.

son, a discovery that flies in the face of the principle of sufficient reason.

Indeed, as I will show later, it turns out that an infinite number of mathematical facts are irreducible, which means no theory explains why they are true. These facts are not just computationally irreducible, they are logically irreducible. The only way to “prove” such facts is to assume them directly as new axioms, without using reasoning at all.

The concept of an “axiom” is closely related to the idea of logical irreducibility. Axioms are mathematical facts that we take as self-evident and do not try to prove from simpler principles. All formal mathematical theories start with axioms and then deduce the consequences of these axioms, which are called theorems. That is how Euclid did things in Alexandria two millennia ago, and his treatise on geometry is the classical model for mathematical exposition.

In ancient Greece, if you wanted to convince your fellow citizens to vote with you on some issue, you had to reason with them—which I guess is how the Greeks came up with the idea that in mathematics you have to prove things rather than just discover them experimentally. In contrast, previous cultures in Mesopotamia and Egypt apparently relied on experiment. Using reason has certainly been an extremely fruitful approach, leading to modern mathematics and mathematical physics and all that

goes with them, including the technology for building that highly logical and mathematical machine, the computer.

So am I saying that this approach that science and mathematics has been following for more than two millennia crashes and burns? Yes, in a sense I am. My counterexample illustrating the limited power of logic and reason, my source of an infinite stream of unprovable mathematical facts, is the number that I call omega.

The Number Omega

THE FIRST STEP on the road to omega came in a famous paper published precisely 250 years after Leibniz’s essay. In a 1936 issue of the *Proceedings of the London Mathematical Society*, Alan M. Turing began the computer age by presenting a mathematical model of a simple, general-purpose, programmable digital computer. He then asked, Can we determine whether or not a computer program will ever halt? This is Turing’s famous halting problem.

Of course, by running a program you can eventually discover that it halts, if it halts. The problem, and it is an extremely fundamental one, is to decide when to give up on a program that does not halt. A great many special cases can be solved, but Turing showed that a general solution is impossible. No algorithm, no mathematical theory, can ever tell us which programs will halt and

which will not. (For a modern proof of Turing’s thesis, see www.sciam.com/ontheweb) By the way, when I say “program,” in modern terms I mean the concatenation of the computer program and the data to be read in by the program.

The next step on the path to the number omega is to consider the ensemble of all possible programs. Does a program chosen at random ever halt? The probability of having that happen is my omega number. First, I must specify how to pick a program at random. A program is simply a series of bits, so flip a coin to determine the value of each bit. How many bits long should the program be? Keep flipping the coin so long as the computer is asking for another bit of input. Omega is just the probability that the machine will eventually come to a halt when supplied with a stream of random bits in this fashion. (The precise numerical value of omega depends on the choice of computer programming language, but omega’s surprising properties are not affected by this choice. And once you have chosen a language, omega has a definite value, just like pi or the number 3.)

Being a probability, omega has to be greater than 0 and less than 1, because some programs halt and some do not. Imagine writing omega out in binary. You would get something like 0.1110100... These bits after the decimal point form an irreducible stream of bits. They are our irreducible mathematical facts (each fact being whether the bit is a 0 or a 1).

Omega can be defined as an infinite sum, and each N -bit program that halts contributes precisely $1/2^N$ to the sum [see box on preceding page]. In other words,

each N -bit program that halts adds a 1 to the N th bit in the binary expansion of omega. Add up all the bits for all programs that halt, and you would get the precise value of omega. This description may make it sound like you can calculate omega accurately, just as if it were the square root of 2 or the number pi. Not so—omega is perfectly well defined and it is a specific number, but it is impossible to compute in its entirety.

We can be sure that omega cannot be computed because knowing omega would let us solve Turing’s halting problem, but we know that this problem is unsolvable. More specifically, knowing the first N bits of omega would enable you to decide whether or not each program up to N bits in size ever halts [see box on page 80]. From this it follows that you need at least an N -bit program to calculate N bits of omega.

Note that I am not saying that it is impossible to compute some digits of omega. For example, if we knew that computer programs 0, 10 and 110 all halt, then we would know that the first digits of omega were 0.111. The point is that the first N digits of omega cannot be computed using a program significantly shorter than N bits long.

Most important, omega supplies us with an infinite number of these irreducible bits. Given any finite program,

no matter how many billions of bits long, we have an infinite number of bits that the program cannot compute. Given any finite set of axioms, we have an infinite number of truths that are unprovable in that system.

Because omega is irreducible, we can immediately conclude that a theory of everything for all of mathematics cannot exist. An infinite number of bits of omega constitute mathematical facts (whether each bit is a 0 or a 1) that cannot be derived from any principles simpler than the string of bits itself. Mathematics therefore has infinite complexity, whereas any individual theory of everything would have only finite complexity and could not capture all the richness of the full world of mathematical truth.

This conclusion does not mean that proofs are no good, and I am certainly not against reason. Just because some things are irreducible does not mean we should give up using reasoning. Irreducible principles—axioms—have always been a part of mathematics. Omega just shows that a lot more of them are out there than people suspected.

So perhaps mathematicians should not try to prove everything. Sometimes they should just add new axioms. That is what you have got to do if you are faced with irreducible facts. The prob-

GOTTFRIED W. LEIBNIZ, commemorated by a statue in Leipzig, Germany, anticipated many of the features of modern algorithmic information theory more than 300 years ago.

lem is realizing that they are irreducible! In a way, saying something is irreducible is giving up, saying that it cannot ever be proved. Mathematicians would rather die than do that, in sharp contrast with their physicist colleagues, who are happy to be pragmatic and to use plausible reasoning instead of rigorous proof. Physicists are willing to add new principles, new scientific laws, to understand new domains of experience.

This raises what I think is an extremely interesting question: Is mathematics like physics?

Mathematics and Physics

THE TRADITIONAL VIEW is that mathematics and physics are quite different. Physics describes the universe and depends on experiment and observation. The particular laws that govern our universe—whether Newton’s laws of motion or the Standard Model of particle physics—must be determined empirically and then asserted like axioms that cannot be logically proved, merely verified.

Mathematics, in contrast, is somehow independent of the universe. Results and theorems, such as the properties of the integers and real numbers, do not depend in any way on the particular nature of reality in which we find ourselves. Mathematical truths would be true in any universe.

A SCIENTIFIC THEORY is like a computer program that predicts our observations of the universe. A useful theory is a compression of the data; from a small number of laws and equations, whole universes of data can be computed.

R. LAKE Zehr / Corbis (top); BUSAN PETERIC (bottom)

GREGORY CHAITIN is a researcher at the IBM Thomas J. Watson Research Center. He is also honorary professor at the University of Buenos Aires and visiting professor at the University of Auckland. He is co-founder, with Andrei N. Kolmogorov, of the field of algorithmic information theory. His nine books include the nontechnical works *Conversations with a Mathematician* (2002) and *Meta Math!* (2005). When he is not thinking about the foundations of mathematics, he enjoys hiking and snowshoeing in the mountains.

Yet both fields are similar. In physics, and indeed in science generally, scientists compress their experimental observations into scientific laws. They then show how their observations can be deduced from these laws. In mathematics, too, something like this happens—mathematicians compress their computational experiments into mathematical axioms, and they then show how to deduce theorems from these axioms.

If Hilbert had been right, mathematics would be a closed system, without room for new ideas. There would be a static, closed theory of everything for all of mathematics, and this would be like a dictatorship. In fact, for mathematics to progress you actually need new ideas and plenty of room for creativity. It does not suffice to grind away, mechanically deducing all the possible consequences of a fixed number of basic principles. I much prefer an open system. I do not like rigid, authoritarian ways of thinking.

Another person who thought math-

ematics is like physics was Imre Lakatos, who left Hungary in 1956 and later worked on philosophy of science in England. There Lakatos came up with a great word, “quasi-empirical,” which means that even though there are no true experiments that can be carried out in mathematics, something similar does take place. For example, the Goldbach conjecture states that any even number greater than 2 can be expressed as the sum of two prime numbers. This conjecture was arrived at experimentally, by noting empirically that it was true for every even number that anyone cared to examine. The conjecture has not yet been proved, but it has been verified up to 10^{14} .

I think that mathematics is quasi-empirical. In other words, I feel that mathematics is different from physics (which is truly empirical) but perhaps not as different as most people think.

I have lived in the worlds of both mathematics and physics, and I never thought there was such a big difference

between these two fields. It is a matter of degree, of emphasis, not an absolute difference. After all, mathematics and physics coevolved. Mathematicians should not isolate themselves. They should not cut themselves off from rich sources of new ideas.

New Mathematical Axioms

THE IDEA OF CHOOSING to add more axioms is not an alien one to mathematics. A well-known example is the parallel postulate in Euclidean geometry: given a line and a point not on the line, there is exactly one line that can be drawn through the point that never intersects the original line. For centuries geometers wondered whether that result could be proved using the rest of Euclid's axioms. It could not. Finally, mathematicians realized that they could substitute different axioms in place of the Euclidean version, thereby producing the non-Euclidean geometries of curved spaces, such as the surface of a sphere or of a saddle.

OMEGA represents a part of mathematics that is in a sense unknowable. A finite computer program can reveal only a finite number of omega's digits; the rest remain shrouded in obscurity.

Other examples are the law of the excluded middle in logic and the axiom of choice in set theory. Most mathematicians are happy to make use of those axioms in their proofs, although others do not, exploring instead so-called intuitionist logic or constructivist mathematics. Mathematics is not a single monolithic structure of absolute truth!

Another very interesting axiom may be the “P not equal to NP” conjecture. P and NP are names for classes of problems. An NP problem is one for which a proposed solution can be verified quickly. For example, for the problem “find the factors of 8,633,” one can quickly verify the proposed solution “97 and 89” by multiplying those two numbers. (There is a technical definition of “quickly,” but those details are not important here.) A P problem is one that can be solved quickly even without being given the solution. The question is—and no one knows the answer—can every NP problem be solved quickly? (Is there a quick way to find the factors of 8,633?) That is, is the class P the same as the class NP? This problem is one of the Clay Millennium Prize Problems for which a reward of \$1 million is on offer.

Computer scientists widely believe that P is not equal to NP, but no proof is known. One could say that a lot of quasi-empirical evidence points to P not being equal to NP. Should P not equal to NP be adopted as an axiom, then? In effect, this is what the computer science community has done. Closely related to this issue is the security of certain cryptographic systems used throughout the world. The systems are believed to be invulnerable to being cracked, but no one can prove it.

Experimental Mathematics

ANOTHER AREA of similarity between mathematics and physics is experimental mathematics: the discovery of new mathematical results by looking at

many examples using a computer. Whereas this approach is not as persuasive as a short proof, it can be more convincing than a long and extremely complicated proof, and for some purposes it is quite sufficient.

In the past, this approach was defended with great vigor by both George Pólya and Lakatos, believers in heuristic reasoning and in the quasi-empirical nature of mathematics. This methodology is also practiced and justified in Stephen Wolfram's *A New Kind of Science* (2002).

Extensive computer calculations can be extremely persuasive, but do they render proof unnecessary? Yes and no.

In fact, they provide a different kind of evidence. In important situations, I would argue that both kinds of evidence are required, as proofs may be flawed, and conversely computer searches may have the bad luck to stop just before encountering a counterexample that disproves the conjectured result.

All these issues are intriguing but far from resolved. It is now 2006, 50 years after this magazine published its article on Gödel's proof, and we still do not know how serious incompleteness is. We do not know if incompleteness is telling us that mathematics should be done somewhat differently. Maybe 50 years from now we will know the answer. ☒

Why Is Omega Incompressible?

I wish to demonstrate that omega is incompressible—that one cannot use a program substantially shorter than N bits long to compute the first N bits of omega. The demonstration will involve a careful combination of facts about omega and the Turing halting problem that it is so intimately related to. Specifically, I will use the fact that the halting problem for programs up to length N bits cannot be solved by a program that is itself shorter than N bits (see www.sciam.com/ontheweb).

My strategy for demonstrating that omega is incompressible is to show that having the first N bits of omega would tell me how to solve the Turing halting problem for programs up to length N bits. It follows from that conclusion that no program shorter than N bits can compute the first N bits of omega. (If such a program existed, I could use it to compute the first N bits of omega and then use those bits to solve Turing's problem up to N bits—a task that is impossible for such a short program.)

Now let us see how knowing N bits of omega would enable me to solve the halting problem—to determine which programs halt—for all programs up to N bits in size. Do this by performing a computation in stages. Use the integer K to label which stage we are at: $K = 1, 2, 3, \dots$

At stage K , run every program up to K bits in size for K seconds. Then compute a halting probability, which we will call $\omega_{K,K}$, based on all the programs that halt by stage K .

$\omega_{K,K}$ will be less than omega because it is based on only a subset of all the programs that halt eventually, whereas omega is based on all such programs.

As K increases, the value of $\omega_{K,K}$ will get closer and closer to the actual value of omega. As it gets closer to omega's actual value, more and more of $\omega_{K,K}$'s first bits will be correct—that is, the same as the corresponding bits of omega.

And as soon as the first N bits are correct, you know that you have encountered every program up to N bits in size that will ever halt. (If there were another such N -bit program, at some later-stage K that program would halt, which would increase the value of $\omega_{K,K}$ to be greater than omega, which is impossible.)

So we can use the first N bits of omega to solve the halting problem for all programs up to N bits in size. Now suppose we could compute the first N bits of omega with a program substantially shorter than N bits long. We could then combine that program with the one for carrying out the $\omega_{K,K}$ algorithm, to produce a program shorter than N bits that solves the Turing halting problem up to programs of length N bits.

But, as stated up front, we know that no such program exists. Consequently, the first N bits of omega must require a program that is almost N bits long to compute them. That is good enough to call omega incompressible or irreducible. (A compression from N bits to almost N bits is not significant for large N .) —G.C.

Historical Perspectives

John von Neumann (1903-1957)

- Contributed to set theory, functional analysis, quantum mechanics, ergodic theory, economics, geometry, hydrodynamics, statistics, analysis, measure theory, ballistics, meteorology, ...
- Invented **game theory** (used in Cold War)
- Re-**axiomatized set theory**
- Principal member of **Manhattan Project**
- Helped design the hydrogen / **fusion bomb**
- **Pioneered modern computer science**
- Originated the “**stored program**”

Ulam Feynman

"Most mathematicians prove what they can; von Neumann proves what he wants."

von Neumann's Legacy

- Re-axiomatized set theory to address **Russell's paradox**
- Independently proved **Godel's second incompleteness theorem**: aximomatic systems are unable to prove their own consistency.
- Addressed **Hilbert's 6th problem**: **axiomatized quantum mechanics** using Hilbert spaces.
- Developed the game-theory based **Mutually-Assured Destruction (MAD)** strategic equilibrium policy – still in effect today!
- von Neumann regular rings, von Neumann bicommutant theorem, von Neumann entropy, **von Neumann programming languages**

Von Neumann Architecture

“Surely there must be a less primitive way of making big changes in the store than by pushing vast numbers of words back and forth through the **von Neumann bottleneck**. Not only is this tube a literal bottleneck for the data traffic of a problem, but, more importantly, it is an **intellectual bottleneck** that has kept us tied to word-at-a-time thinking instead of encouraging us to think in terms of the larger conceptual units of the task at hand. Thus programming is basically planning and detailing the enormous traffic of words through the Von Neumann bottleneck, and much of that traffic concerns not significant data itself, but where to find it.”

Go Forth and Replicate

Birds do it, bees do it,
but could machines do it?
New computer simulations
suggest that the answer is yes

Apples beget apples, but can machines beget machines? Today it takes an elaborate manufacturing apparatus to build even a simple machine. Could we endow an artificial device with the ability to multiply on its own? Self-replication has long been considered one of the fundamental properties separating the living from the nonliving. Historically our limited understanding of how biological reproduction works has given it an aura of mystery and made it seem unlikely that it would ever be done by a man-made object. It is reported that when René Descartes averred to Queen Christina of Sweden that animals were just another form of mechanical automata, Her Majesty pointed to a clock and said, “See to it that it produces offspring.”

The problem of machine self-replication moved from philosophy into the realm of science and engineering in the late 1940s with the work of eminent mathematician and physicist John von Neumann. Some researchers have actually constructed physical replicators. Forty years ago, for example, geneticist Lionel Penrose and his son, Roger (the famous physicist), built small assemblies of plywood that exhibited a simple form of self-replication [see “Self-Reproducing Machines,” by Lionel

Penrose; *SCIENTIFIC AMERICAN*, June 1959]. But self-replication has proved to be so difficult that most researchers study it with the conceptual tool that von Neumann developed: two-dimensional cellular automata.

Implemented on a computer, cellular automata can simulate a huge variety of self-replicators in what amount to austere universes with different laws of physics from our own. Such models free researchers from having to worry about logistical issues such as energy and physical construction so that they can focus on the fundamental questions of information flow. How is a living being able to replicate unaided, whereas mechanical objects must be constructed by humans? How does replication at the level of an organism emerge from the numerous interactions in tissues, cells and molecules? How did Darwinian evolution give rise to self-replicating organisms?

The emerging answers have inspired the development of self-repairing silicon chips [see *box on page 40*] and autocatalyzing molecules [see “Synthetic Self-Replicating Molecules,” by Julius Rebek, Jr.; *SCIENTIFIC AMERICAN*, July 1994]. And this may be just the beginning. Researchers in the field of nanotechnology have long proposed that self-replication will be crucial to manu-

By Moshe Sipper and James A. Reggia

facturing molecular-scale machines, and proponents of space exploration see a macroscopic version of the process as a way to colonize planets using in situ materials. Recent advances have given credence to these futuristic-sounding ideas. As with other scientific disciplines, including genetics, nuclear energy and chemistry, those of us who study self-replication face the twofold challenge of creating replicating machines and avoiding dystopian pre-

scription could be used in two distinct ways: first, as the instructions whose interpretation leads to the construction of an identical copy of the device; next, as data to be copied, uninterpreted, and attached to the newly created child so that it too possesses the ability to self-replicate. With this two-step process, the self-description need not contain a description of itself. In the architectural analogy, the blueprint would include a plan for building a pho-

the cellular-automata world. All decisions and actions take place locally; cells do not know directly what is happening outside their immediate neighborhood.

The apparent simplicity of cellular automata is deceptive; it does not imply ease of design or poverty of behavior. The most famous automata, John Horton Conway's Game of Life, produces amazingly intricate patterns. Many questions about the dynamic behavior of cellular

cells contains a +, then the cell becomes a +; otherwise it becomes vacant. With this rule, a single + grows into four more +'s, each of which grows likewise, and so forth.

Such weedlike proliferation does not shed much light on the principles of replication, because there is no significant machine. Of course, that invites the question of how you would tell a "significant" machine from a trivially prolific automata. No one has yet devised a satisfactory answer. What is clear, however, is that the replicating structure must in some sense be complex. For example, it must consist of multiple, diverse components whose interactions collectively bring about replication—the proverbial "whole must be greater than the sum of the parts." The existence of multiple distinct components permits a self-description to be stored within the replicating structure.

In the years since von Neumann's seminal work, many researchers have probed the domain between the complex and the trivial, developing replicators that require fewer components, less space or simpler rules. A major step forward was taken in 1984 when Christopher G. Langton, then at the University of Michigan, observed that looplike storage devices—which had formed modules of earlier self-replicating machines—could be programmed to replicate on their own. These devices typically consist of two pieces: the loop itself, which is a string of components that circulate around a rectangle, and a construction arm, which protrudes from a corner of the rectangle into the surrounding space. The circulating components constitute a recipe for the loop—for example, "go three squares ahead, then turn left." When this recipe reaches the construction arm, the automata rules make a copy of it. One copy continues around the loop; the other goes down the arm, where it is interpreted as instructions.

By giving up the requirement of universal construction, which was central to von Neumann's approach, Langton showed that a replicator could be constructed from just seven unique components occupying only 86 cells. Even smaller and simpler self-replicating loops have been devised by one of us (Reggia) and our colleagues [see box on next page]. Be-

cause they have multiple interacting components and include a self-description, they are not trivial. Intriguingly, asymmetry plays an unexpected role: the rules governing replication are often simpler when the components are not rotational-ly symmetric than when they are.

Emergent Replication

ALL THESE SELF-REPLICATING structures have been designed through ingenuity and much trial and error. This process is arduous and often frustrating; a small change to one of the rules results in an entirely different global behavior, most likely the disintegration of the structure in question. But recent work has gone beyond the direct-design approach. Instead of tailoring the rules to suit a par-

ticular type of structure, researchers have experimented with various sets of rules, filled the cellular-automata grid with a "primordial soup" of randomly selected components and checked whether self-replicators emerged spontaneously.

In 1997 Hui-Hsien Chou, now at Iowa State University, and Reggia noticed that as long as the initial density of the free-floating components was above a certain threshold, small self-replicating loops reliably appeared. Loops that collided underwent annihilation, so there was an ongoing process of death as well as birth. Over time, loops proliferated, grew in size and evolved through mutations triggered by debris from past collisions. Although the automata rules were deterministic, these mutations were effectively random,

Her Majesty pointed to a clock and said, "See to it that it produces offspring."

dictions of devices running amok. The knowledge we gain will help us separate good technologies from destructive ones.

Playing Life

SCIENCE-FICTION STORIES often depict cybernetic self-replication as a natural development of current technology, but they gloss over the profound problem it poses: how to avoid an infinite regress.

A system might try to build a clone using a blueprint—that is, a self-description. Yet the self-description is part of the machine, is it not? If so, what describes the description? And what describes the description of the description? Self-replication in this case would be like asking an architect to make a perfect blueprint of his or her own studio. The blueprint would have to contain a miniature version of the blueprint, which would contain a miniature version of the blueprint and so on. Without this information, a construction crew would be unable to re-create the studio fully; there would be a blank space where the blueprint had been.

Von Neumann's great insight was an explanation of how to break out of the infinite regress. He realized that the self-de-

scription could be used in two distinct ways: first, as the instructions whose interpretation leads to the construction of an identical copy of the device; next, as data to be copied, uninterpreted, and attached to the newly created child so that it too possesses the ability to self-replicate. With this two-step process, the self-description need not contain a description of itself. In the architectural analogy, the blueprint would include a plan for building a pho-

copy machine. Once the new studio and the photocopier were built, the construction crew would simply run off a copy of the blueprint and put it into the new studio.

Living cells use their self-description, which biologists call the genotype, in exactly these two ways: transcription (DNA is copied mostly uninterpreted to form mRNA) and translation (mRNA is interpreted to build proteins). Von Neumann made this transcription-translation distinction several years before molecular biologists did, and his work has been crucial in understanding self-replication in nature.

To prove these ideas, von Neumann and mathematician Stanislaw M. Ulam came up with the idea of cellular automata. A cellular-automata simulation involves a chessboardlike grid of squares, or cells, each of which is either empty or occupied by one of several possible components. At discrete intervals of time, each cell looks at itself and its neighbors and decides whether to metamorphose into a different component. In making this decision, the cell follows relatively simple rules, which are the same for all cells. These rules constitute the basic physics of

automata are formally unsolvable. To see how a pattern will unfold, you need to simulate it fully [see *Mathematical Games*, by Martin Gardner; *SCIENTIFIC AMERICAN*, October 1970 and February 1971; and "The Ultimate in Anty-Particles," by Ian Stewart, July 1994]. In its own way, a cellular-automata model can be just as complex as the real world.

Copy Machines

WITHIN CELLULAR AUTOMATA, self-replication occurs when a group of components—a "machine"—goes through a sequence of steps to construct a nearby duplicate of itself. Von Neumann's machine was based on a universal constructor, a machine that, given the appropriate instructions, could create any pattern. The constructor consisted of numerous types of components spread over tens of thousands of cells and required a book-length manuscript to be specified. It has still not been simulated in its entirety, let alone actually built, on account of its complexity. A constructor would be even more complicated in the Game of Life because the functions performed by single cells in von Neumann's model—such as transmission of signals and generation of new components—have to be performed by composite structures in Life.

Going to the other extreme, it is easy to find trivial examples of self-replication. For example, suppose a cellular automata has only one type of component, labeled +, and that each cell follows only a single rule: if exactly one of the four neighboring

MOSHE SIPPER and JAMES A. REGGIA share a long-standing interest in how complex systems can self-organize. Sipper is a senior lecturer in the department of computer science at Ben-Gurion University in Israel and a visiting researcher at the Logic Systems Laboratory of the Swiss Federal Institute of Technology in Lausanne. He is interested mainly in bio-inspired computational paradigms such as evolutionary computation, self-replicating systems and cellular computing. Reggia is a professor of computer science and neurology, working in the Institute for Advanced Computer Studies at the University of Maryland. In addition to studying self-replication, he conducts research on computational models of the brain and its disorders, such as stroke.

because the system was complex and the components started in random locations.

Such loops are intended as abstract machines and not as simulacra of anything biological, but it is interesting to compare them with biomolecular structures. A loop loosely resembles circular DNA in bacteria, and the construction arm acts as the enzyme that catalyzes DNA replication. More important, replicating loops illustrate how complex global behaviors can arise from simple local in-

teractions. For example, components move around a loop even though the rules say nothing about movement; what is actually happening is that individual cells are coming alive, dying or metamorphosing in such a way that a pattern is eliminated from one position and reconstructed elsewhere—a process that we perceive as motion. In short, cellular automata act locally but appear to think globally. Much the same is true of molecular biology.

In a recent computational experiment,

Jason Lohn, now at the NASA Ames Research Center, and Reggia experimented not with different structures but with different sets of rules. Starting with an arbitrary block of four components, they found they could determine a set of rules that made the block self-replicate. They discovered these rules via a genetic algorithm, an automated process that simulates Darwinian evolution.

The most challenging aspect of this work was the definition of the so-called

fitness function—the criteria by which sets of rules were judged, thus separating good solutions from bad ones and driving the evolutionary process toward rule sets that facilitated replication. You cannot simply assign high fitness to those sets of rules that cause a structure to replicate, because none of the initial rule sets is likely to allow for replication. The solution was to devise a fitness function composed of a weighted sum of three measures: a growth measure (the extent to which

each component type generates an increasing supply of that component), a relative position measure (the extent to which neighboring components stay together) and a replicant measure (a function of the number of actual replicators present). With the right fitness function, evolution can turn rule sets that are sterile into ones that are fecund; the process usually takes 150 or so generations.

Self-replicating structures discovered in this fashion work in a fundamentally

different way than self-replicating loops do. For example, they move and deposit copies along the way—unlike replicating loops, which are essentially static. And although these newly discovered replicators consist of multiple, locally interacting components, they do not have an identifiable self-description—there is no obvious genome. The ability to replicate without a self-description may be relevant to questions about how the earliest biological

Continued on page 43

BUILD YOUR OWN REPLICATOR

SIMULATING A SMALL self-replicating loop using an ordinary chess set is a good way to get an intuitive sense of how these systems work. This particular cellular-automata model has four different types of components: pawns, knights, bishops and rooks. The machine initially comprises four pawns, a knight and a bishop. It has two parts: the loop itself, which consists of a two-by-two square, and a construction arm, which sticks out to the right.

The knight and bishop represent the self-description: the knight, whose orientation is significant, determines which direction to grow, while the bishop tags along and determines how long the side of the loop should be. The pawns are fillers that define the rest of the shape of the loop, and the rook is a transient signal to guide the growth of a new construction arm.

As time progresses, the knight and bishop circulate counterclockwise around the loop. Whenever they encounter the arm, one copy goes out the arm while the original continues around the loop.

HOW TO PLAY: You will need two chessboards: one to represent the current configuration, the other to show the next configuration. For each round, look at each square of the current configuration, consult the rules and place the appropriate piece in the corresponding square on the other board. Each piece metamorphoses depending on its identity and that of the four squares immediately to the left, to the right, above and below. When you have reviewed each square and set up the next configuration, the round is over. Clear the first board and repeat. Because the rules are complicated, it takes a bit of patience at first. You can also view the simulation at islwww.epfl.ch/chess

The direction in which a knight faces is significant. In the drawings here, we use standard chess conventions to indicate the orientation of the knight: the horse's muzzle points forward. If no rule explicitly applies, the contents of the square stay the same. Squares on the edge should be treated as if they have adjacent empty squares off the board. —*M.S. and J.A.R.*

STAGES OF REPLICATION

INITIALLY, the self-description, or "genome"—a knight followed by a bishop—is poised at the start of the construction arm.

1 The knight and bishop move counterclockwise around the loop. A clone of the knight heads out the arm.

2 The original knight-bishop pair continues to circulate. The bishop is cloned and follows the new knight out the arm.

3 The knight triggers the formation of two corners of the child loop. The bishop tags along, completing the gene transfer.

4 The knight forges the remaining corner of the child loop. The loops are connected by the construction arm and a knight-errant.

5 The knight-errant moves up to endow the parent with a new arm. A similar process, one step delayed, begins for the child loop.

6 The knight-errant, together with the original knight-bishop pair, conjures up a rook. Meanwhile the old arm is erased.

7 The rook kills the knight and generates the new, upward arm. Another rook prepares to do the same for the child.

8 At last the two loops are separate and whole. The self-descriptions continue to circulate, but otherwise all is calm.

9 The parent prepares to give birth again. In the following step, the child too will begin to replicate.

KNIGHT

IF THERE is a bishop just behind or to the left of the knight, replace the knight with another bishop.

OTHERWISE, if at least one of the neighboring squares is occupied, remove the knight and leave the square empty.

PAWN

IF THERE is a neighboring knight, replace the pawn with a knight with a certain orientation, as follows:

IF A NEIGHBORING knight is facing away from the pawn, the new knight faces the opposite way.

OTHERWISE, if there is exactly one neighboring pawn, the new knight faces that pawn.

OTHERWISE the new knight faces in the same direction as the neighboring knight.

BISHOP OR ROOK

REPLACE IT with a pawn.

EMPTY SQUARE

IF THERE are two neighboring knights and either faces the empty square, fill the square with a rook.

IF THERE is only one neighboring knight and it faces the square, fill the square with a knight rotated 90 degrees counterclockwise.

IF THERE is a neighboring knight and its left side faces the square, and the other neighbors are empty, fill the square with a pawn.

IF THERE is a neighboring rook, and the other neighbors are empty, fill the square with a pawn.

IF THERE are three neighboring pawns, fill the square with a knight facing the fourth, empty neighbor.

ROBOT, HEAL THYSELF

Computers that fix themselves are the first application of artificial self-replication

LAUSANNE, SWITZERLAND—Not many researchers encourage the wanton destruction of equipment in their labs. Daniel Mange, however, likes it when visitors walk up to one of his inventions and press the button marked KILL. The lights on the panel go out; a small box full of circuitry is toast. Early in May his team unveiled its latest contraption at a science festival here—a wall-size digital clock whose components you can zap at will—and told the public: Give it your best shot. See if you can crash the system.

The goal of Mange and his team is to instill electronic circuits with the ability to take a lickin' and keep on tickin'—just like living things. Flesh-and-blood creatures might not be so good at calculating π to the millionth digit, but they can get through the day without someone pressing Ctrl-Alt-Del. Combining the precision of digital hardware with the resilience of biological wetware is a leading challenge for modern electronics.

Electronics engineers have been working on fault-tolerant circuits ever since there were electronics engineers [see "Redundancy in Computers," by William H. Pierce, SCIENTIFIC AMERICAN, February 1964]. Computer modems would still be dribbling data at 1200 baud if it weren't for error detection and correction. In many applications, simple quality-control checks, such as extra data bits, suffice. More complex systems provide entire backup computers. The space shuttle, for example, has five processors. Four of them perform the same calculations; the fifth checks whether they agree and pulls the plug on any dissenter.

The problem with these systems, though, is that they rely on centralized control. What if that control unit goes bad?

Nature has solved that problem through radical decentralization. Cells in the body are all basically identical; each takes on a specialized task, performs it autonomously and, in the event of infection or failure, commits hara-kiri so that its tasks can be taken up by new cells. These are the attributes that Mange, a professor at the Swiss Federal Institute of Technology here, and others have sought since 1993 to emulate in circuitry, as part of the "Embryonics" (embryonic electronics) project.

One of their earlier inventions, the MICTREE (microinstruction tree) artificial cell, consisted of a simple processor and four bits of data storage. The cell is contained in a plastic box roughly the size of a pack of Post-its. Electrical contacts run along the sides so that cells can be snapped together like Legos. As in cellular automata, the models used to study the theory of self-replication, the MICTREE cells are connected only to their immediate neighbors. The communication burden on each cell is thus independent of the total number of cells. The system, in other words, is easily scalable—unlike many parallel-computing architectures.

Cells follow the instructions in their "genome," a program written in a subset of the Pascal computer language. Like their biological antecedents, the cells all contain the exact same genome and execute part of it based on their position within the array, which each cell calculates relative to its neighbors. Waste-

ful though it may seem, this redundancy allows the array to withstand the loss of any cell. Whenever someone presses the KILL button on a cell, that cell shuts down, and its left and right neighbors become directly connected. The right neighbor recalculates its position and starts executing the deceased's program. Its tasks, in turn, are taken up by the next cell to the right, and so on, until a cell designated as a spare is pressed into service.

Writing programs for any parallel processor is tricky, but the MICTREE array requires an especially unconventional approach. Instead of giving explicit instructions, the programmer must devise simple rules out of which the desired function will emerge. Being Swiss, Mange demonstrates by building a superreliable stopwatch. Displaying minutes and seconds requires four cells in a row, one for each digit. The genome allows for two cell types: a counter from zero to nine and a counter from zero to five. An oscillator feeds one pulse per second into the rightmost cell. After 10 pulses, this cell cycles back to zero and sends a pulse to the cell on its left, and so on down the line. The watch takes up part of an array of 12 cells; when you kill one, the clock transplants itself one cell over and carries on. Obviously, though, there is a limit to its resilience: the whole thing will fail after, at most, eight kills.

The prototype MICTREE cells are hardwired, so their processing power cannot be tailored to a specific application. In a finished product, cells would instead be implemented on a field-programmable gate array, a grid of electronic components that can be reconfigured on the fly [see "Configurable Computing," by John Villasenor and William H. Mangione-Smith, SCIENTIFIC AMERICAN, June 1997]. Mange's team is now custom-designing a gate array,

known as MUXTREE (multiplexer tree), that is optimized for artificial cells. In the biological metaphor, the components of this array are the "molecules" that constitute a cell. Each consists of a logic gate, a data bit and a string of configuration bits that determines the function of this gate.

Building a cell out of such molecules offers not only flexibility but also extra endurance. Each molecule contains two copies of the gate and three of the storage bit. If the two gates ever give different results, the molecule kills itself for the greater good of the cell. As a last gasp, the molecule sends its data bit (preserved by the triplicate storage) and configuration to its right neighbor, which does the same, and the process continues until the right-most molecule transfers its data to a spare. This second level of fault tolerance prevents a single error from wiping out an entire cell.

A total of 2,000 molecules, divided into four 20-by-25 cells, make up the BioWall—the giant digital clock that Mange's team has just put on display. Each molecule is enclosed in a small box and includes a KILL button and an LED display. Some molecules are configured to perform computations; others serve as pixels in the clock display. Making liberal use of the KILL buttons, I did my utmost to crash the system, something I'm usually quite good at. But the plucky clock just wouldn't submit. The clock display did start to look funny—numerals bent over as their pixels shifted to the right—but at least it was still legible, unlike most faulty electronic signs.

That said, the system did suffer from display glitches, which Mange attributed mainly to timing problems. Although the processing power is decentralized, the cells still rely on a central oscillator to coordinate their communications; sometimes they fall out of sync. Another Embryonics team, led by Andy Tyrrell of the University of York in England, has been studying making the cells asynchronous, like their biological counterparts. Cells would generate handshaking signals to orchestrate data transfers. The present system is also unable to catch certain types of error, including damaged configuration strings. Tyrrell's team has proposed adding watchdog molecules—an immune system—that would monitor the configurations (and one another) for defects.

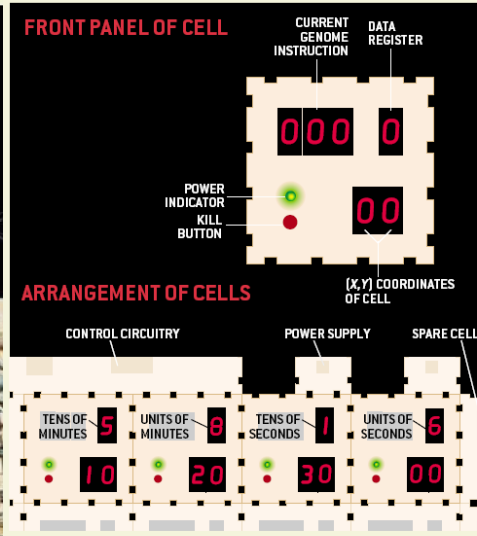

Although these systems demand an awful lot of overhead, so do other fault-tolerance technologies. "While Embryonics appears to be heavy on redundancy, it actually is not that bad when compared to other systems," Tyrrell argues. Moreover, MUXTREE should be easier to scale down to the nano level; the "molecules" are simple enough to really be molecules. Says Mange, "We are preparing for the situation where electronics will be at the same scale as biology."

On a philosophical level, Embryonics comes very close to the dream of building a self-replicating machine. It may not be quite as dramatic as a robot that can go down to Radio Shack, pull parts off the racks, and take them home to resolder a connection or build a loving mate. But the effect is much the same. Letting machines determine their own destiny—whether reconfiguring themselves on a silicon chip or reprogramming themselves using a neural network or genetic algorithm—sounds scary, but perhaps we should be gratified that machines are becoming more like us: imperfect, fallible but stubbornly resourceful.

—George Musser, imperfect but resourceful staff editor and writer

CRASH-PROOF COMPUTER is a two-dimensional array of artificial cells, each one a simple processor. In this application, four cells work together as a stopwatch, one cell per digit. Each cell counts up to either five or nine, depending on its coordinates within the array. The rest of the cells in the array are spares that take over if a cell fails or is killed. The Biodule 601 cells shown here are based on the MICTREE architecture described in the text.

replicators originated. In a sense, researchers are seeing a continuum between nonliving and living structures.

Many researchers have tried other computational models besides the traditional cellular automata. In asynchronous cellular automata, cells are not updated in concert; in nonuniform cellular automata, the rules can vary from cell to cell. Another approach altogether is Core War [see Computer Recreations, by A. K. Dewdney; SCIENTIFIC AMERICAN, May 1984] and its successors, such as ecologist Thomas S. Ray's Tierra system. In these

simulations the "organisms" are computer programs that vie for processor time and memory. Ray has observed the emergence of "parasites" that co-opt the self-replication code of other organisms.

Getting Real

SO WHAT GOOD are these machines? Von Neumann's universal constructor can compute in addition to replicating, but it is an impractical beast. A major advance has been the development of simple yet useful replicators. In 1995 Gianluca Tempesti of the Swiss Federal Institute of Technology in Lausanne simplified the loop self-description so it could be interlaced with a small program—in this case, one that would spell the acronym of his lab, "LSL." His insight was to create automata rules that allow loops to replicate in two stages. First the loop, like Langton's loop, makes a copy of itself. Once finished, the daughter loop sends a signal back to its parent, at which point the parent sends the instructions for writing out the letters.

Drawing letters was just a demonstration. The following year Jean-Yves Perrier, Jacques Zahnd and one of us (Sipper) designed a self-replicating loop with universal computational capabilities—that is, with the computational power of a universal Turing machine, a highly simplified but fully capable computer. This loop has two "tapes," or long strings of compo-

nents, one for the program and the other for data. The loops can execute an arbitrary program in addition to self-replicating. In a sense, they are as complex as the computer that simulates them. Their main limitation is that the program is copied unchanged from parent to child, so that all loops carry out the same set of instructions.

In 1998 Chou and Reggia swept away this limitation. They showed how self-replicating loops carrying distinct information, rather than a cloned program, can be used to solve a problem known as satisfiability. The loops can be used to determine whether the variables in a logical ex-

pression can be assigned values such that the entire expression evaluates to "true." This problem is NP-complete—in other words, it belongs to the family of nasty puzzles, including the famous traveling-salesman problem, for which there is no known efficient solution. In Chou and Reggia's cellular-automata universe, each replicator received a different partial solution. During replication, the solutions mutated, and replicators with promising solutions were allowed to proliferate while those with failed solutions died out.

In a sense, researchers are seeing a continuum between nonliving and living structures.

Although various teams have created cellular automata in electronic hardware, such systems are probably too wasteful for practical applications; automata were never really intended to be implemented directly. Their purpose is to illuminate the underlying principles of replication and, by doing so, inspire more concrete efforts. The loops provide a new paradigm for de-

signing a parallel computer from either transistors or chemicals [see "Computing with DNA," by Leonard M. Adleman; SCIENTIFIC AMERICAN, August 1998]. In 1980 a NASA team led by Robert Freitas, Jr., proposed planting a factory on the moon that would replicate itself, using local lunar materials, to populate a large area exponentially. Indeed, a similar probe could colonize the entire galaxy, as physicist Frank J. Tipler of Tulane University has argued. In the nearer term, computer scientists and engineers have experimented with the automated design of robots [see "Dawn of a New Species?" by George

Musser; SCIENTIFIC AMERICAN, November 2000]. Although these systems are not truly self-replicating—the offspring are much simpler than the parent—they are a first step toward fulfilling the queen of Sweden's request.

Should physical self-replicating machines become practical, they and related technologies will raise difficult issues, including the *Terminator* film scenario in which artificial creatures outcompete natural ones. We prefer the more optimistic, and more probable, scenario that replicators will be harnessed to the benefit of humanity [see "Will Robots Inherit the Earth?" by Marvin Minsky; SCIENTIFIC AMERICAN, October 1994]. The key will be taking the advice of 14th-century English philosopher William of Ockham: *entia non sunt multiplicanda praeter necessitatem*—entities are not to be multiplied beyond necessity. SA

John von Neumann Institute for Computing (NIC)

The John von Neumann Institute for Computing (NIC) is a joint foundation of [Forschungszentrum Jülich](#) and [Deutsches Elektronen-Synchrotron DESY](#) to support supercomputer-aided scientific research and development. Since April 2006, the [GSI Helmholtzzentrum für Schwerionenforschung](#) joined NIC as a contract partner. NIC takes over the functions and tasks of the High Performance Computer Centre (HLRZ) established in 1987 and continues this centre's successful work in the field of supercomputing and its applications.

- **Provision of supercomputer capacity** for [projects](#) in science, research and industry in the fields of modelling and computer simulation including their methods.
Research proposals can be submitted by German scientists and by partners in the EU projects DEISA and I3HP.
There is also an [Offer to the New Member States and candidate countries of the European Union](#).
- The supercomputers with the required information technology infrastructure (software, data storage, networks) are operated by the [Jülich Supercomputing Centre \(JSC\)](#) in Jülich and by the [Centre for Parallel Computing at DESY in Zeuthen](#).
- **Supercomputer-oriented research and development** in selected fields of physics and other sciences, especially in elementary-particle physics, by [research groups](#) for supercomputing applications.
- **Education and training in the fields of scientific computing** by [symposia, workshops, summer schools, seminars, courses, and guest programs for scientists and students](#).

Introduction

The recent development of various methods of modulation such as PCM and PPM which exchange bandwidth for signal-to-noise ratio has intensified the interest in a general theory of communication. A basis for such a theory is contained in the important papers of Nyquist¹ and Hartley² on this subject. In the present paper we will extend the theory to include a number of new factors, in particular the effect of noise in the channel, and the savings possible due to the statistical structure of the original message and due to the nature of the final destination of the information.

The fundamental problem of communication is that of reproducing at one point either exactly or approximately a message selected at another point. Frequently the messages have meaning; that is they refer to or are correlated according to some system with certain physical or conceptual entities. These semantic aspects of communication are irrelevant to the engineering problem. The significant aspect is that the actual message is one selected from a set of possible messages. The system must be designed to operate for each possible selection, not just the one which will actually be chosen since this is unknown at the time of design.

¹ Nyquist, H., "Certain Factors Affecting Telegraph Speed," *Bell System Technical Journal*, April 1924, p. 324; "Certain Topics in Telegraph Transmission Theory," *A.I.E.E. Trans.*, v. 47, April 1928, p. 617.

² Hartley, R. V. L., "Transmission of Information," *Bell System Technical Journal*, July 1928, p. 535.

If the number of messages in the set is finite then this number or any monotonic function of this number can be regarded as a measure of the information produced when one message is chosen from the set, all choices being equally likely. As was pointed out by Hartley the most natural choice is the logarithmic function. Although this definition must be generalized considerably when we consider the influence of the statistics of the message and when we have a continuous range of messages, we will in all cases use an essentially logarithmic measure.

The logarithmic measure is more convenient for various reasons:

1. It is practically more useful. Parameters of engineering importance such as time, bandwidth, number of relays, etc., tend to vary linearly with the logarithm of the number of possibilities. For example, adding one relay to a group doubles the number of possible states of the relays. It adds 1 to the base 2 logarithm of this number. Doubling the time roughly squares the number of possible messages, or doubles the logarithm, etc.
2. It is nearer to our intuitive feeling as to the proper measure. This is closely related to (1) since we intuitively measure entities by linear comparison with common standards. One feels, for example, that two punched cards should have twice the capacity of one for information storage, and two identical channels twice the capacity of one for transmitting information.
3. It is mathematically more suitable. Many of the limiting operations are simple in terms of the logarithm but would require clumsy restatement in terms of the number of possibilities.

The choice of a logarithmic base corresponds to the choice of a unit for measuring information. If the base 2 is used the resulting units may be called binary digits, or more briefly bits, a word suggested by J. W. Tukey. A device with two stable positions, such as a relay or a flip-flop circuit, can store one bit of information. N such devices can store N bits, since the total number of possible states is 2^N and $\log_2 2^N = N$. If the base 10 is used the units may be called decimal digits. Since

$$\begin{aligned}\log_2 M &= \log_{10} M / \log_{10} 2 \\ &= 3.32 \log_{10} M,\end{aligned}$$

Discrete Noiseless Systems

1. The Discrete Noiseless Channel

Teletype and telegraphy are two simple examples of a discrete channel for transmitting information. Generally, a discrete channel will mean a system whereby a sequence of choices from a finite set of elementary symbols $S_1 \cdot \cdot \cdot S_n$ can be transmitted from one point to another. Each of the symbols S_i is assumed to have a certain duration in time t_i seconds (not necessarily the same for different S_i , for example the dots and dashes in telegraphy). It is not required that all possible sequences of the S_i be capable of transmission on the system; certain sequences only may be allowed. These will be possible signals for the channel. Thus in telegraphy suppose the symbols are: (1) A dot, consisting of line closure for a unit of time and then line open for a unit of time; (2) A dash, consisting of three time units of closure and one unit open; (3) A letter space consisting of, say, three units of line open; (4) A word space of six units of line open. We might place the restriction on allowable sequences that no spaces follow each other (for if two letter spaces are adjacent, they are identical with a word space). The question we now consider is how one can measure the capacity of such a channel to transmit information.

In the teletype case where all symbols are of the same duration, and any sequence of the 32 symbols is allowed, the answer is easy. Each symbol represents five bits of information. If the system

transmits n symbols per second it is natural to say that the channel has a capacity of $5n$ bits per second. This does not mean that the teletype channel will always be transmitting information at this rate — this is the maximum possible rate and whether or not the actual rate reaches this maximum depends on the source of information which feeds the channel, as will appear later.

In the more general case with different lengths of symbols and constraints on the allowed sequences, we make the following definition: The capacity C of a discrete channel is given by

$$C = \lim_{T \rightarrow \infty} \frac{\log N(T)}{T}$$

where $N(T)$ is the number of allowed signals of duration T .

It is easily seen that in the teletype case this reduces to the previous result. It can be shown that the limit in question will exist as a finite number in most cases of interest. Suppose all sequences of the symbols $S_1, \cdot \cdot \cdot, S_n$ are allowed and these symbols have durations $t_1, \cdot \cdot \cdot, t_n$. What is the channel capacity? If $N(t)$ represents the number of sequences of duration t we have

$$N(t) = N(t - t_1) + N(t - t_2) + \cdot \cdot \cdot + N(t - t_n).$$

The total number is equal to the sum of the numbers of sequences ending in $S_1, S_2, \cdot \cdot \cdot, S_n$ and these are $N(t - t_1), N(t - t_2), \cdot \cdot \cdot, N(t - t_n)$, respectively. According to a well-known result in finite differences, $N(t)$ is the asymptotic for large t to AX_0^t where A is constant and X_0 is the largest real solution of the characteristic equation:

$$X^{-t_1} + X^{-t_2} + \cdot \cdot \cdot + X^{-t_n} = 1$$

and therefore

$$C = \lim_{T \rightarrow \infty} \frac{\log AX_0^T}{T} = \log X_0.$$

In case there are restrictions on allowed sequences we may still often obtain a difference equation of this type and find C from the characteristic equation. In the telegraphy case mentioned above

$$N(t) = N(t - 2) + N(t - 4) + N(t - 5) + N(t - 7) \\ + N(t - 8) + N(t - 10)$$

a decimal digit is about $3\frac{1}{3}$ bits. A digit wheel on a desk computing machine has ten stable positions and therefore has a storage capacity of one decimal digit. In analytical work where integration and differentiation are involved the base e is sometimes useful. The resulting units of information will be called natural units. Change from the base a to base b merely requires multiplication by $\log_b a$.

By a communication system we will mean a system of the type indicated schematically in Fig. 1. It consists of essentially five parts:

1. An *information source* which produces a message or sequence of messages to be communicated to the receiving terminal. The message may be of various types: (a) A sequence of letters as in a telegraph or teletype system; (b) A single function of time $f(t)$ as in radio or telephony; (c) A function of time and other variables as in black and white television — here the message may be thought of as a function $f(x, y, t)$ of two space coordinates and time, the light intensity at point (x, y) and time t on a pickup tube plate; (d) Two or more functions of time, say $f(t), g(t), h(t)$ — this is the case in “three-dimensional” sound transmission or if the system is intended to service several individual channels in multiplex; (e) Several functions of several variables — in color television the message consists of three functions $f(x, y, t), g(x, y, t), h(x, y, t)$ defined in a three-dimensional continuum — we may also think of these three functions as components of a vector field defined in the region — similarly, several black and white television sources would produce “messages” consisting of a number of functions of three variables; (f) Various combinations also occur, for example in television with an associated audio channel.

2. A *transmitter* which operates on the message in some way to produce a signal suitable for transmission over the channel. In telephony this operation consists merely of changing sound pressure into a proportional electrical current. In telegraphy we have an encoding operation which produces a sequence of dots, dashes and spaces on the channel corresponding to the message. In a multiplex PCM system the different speech functions must be sampled, compressed, quantized and encoded, and finally inter-

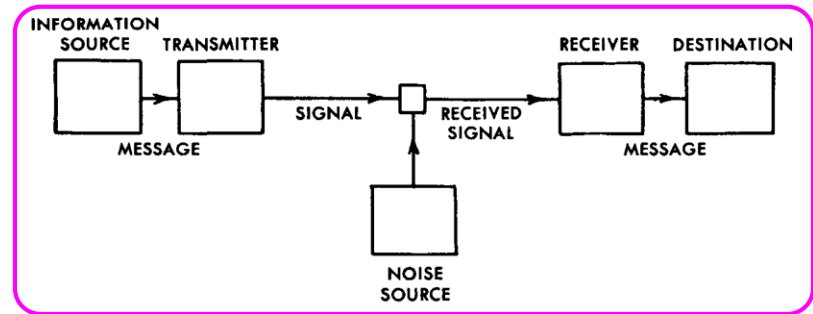

Fig. 1. — Schematic diagram of a general communication system.

leaved properly to construct the signal. Vocoder systems, television and frequency modulation are other examples of complex operations applied to the message to obtain the signal.

3. The *channel* is merely the medium used to transmit the signal from transmitter to receiver. It may be a pair of wires, a coaxial cable, a band of radio frequencies, a beam of light, etc. During transmission, or at one of the terminals, the signal may be perturbed by noise. This is indicated schematically in Fig. 1 by the noise source acting on the transmitted signal to produce the received signal.

4. The *receiver* ordinarily performs the inverse operation of that done by the transmitter, reconstructing the message from the signal.

5. The *destination* is the person (or thing) for whom the message is intended.

We wish to consider certain general problems involving communication systems. To do this it is first necessary to represent the various elements involved as mathematical entities, suitably idealized from their physical counterparts. We may roughly classify communication systems into three main categories: discrete, continuous and mixed. By a discrete system we will mean one in which both the message and the signal are a sequence of discrete symbols. A typical case is telegraphy where the message is a sequence of letters and the signal a sequence of dots, dashes and spaces. A continuous system is one in which the

Suppose we have a set of possible events whose probabilities of occurrence are p_1, p_2, \dots, p_n . These probabilities are known but that is all we know concerning which event will occur. Can we find a measure of how much "choice" is involved in the selection of the event or of how uncertain we are of the outcome?

If there is such a measure, say $H(p_1, p_2, \dots, p_n)$, it is reasonable to require of it the following properties:

1. H should be continuous in the p_i .
2. If all the p_i are equal, $p_i = \frac{1}{n}$, then H should be a monotonic increasing function of n . With equally likely events there is more choice, or uncertainty, when there are more possible events.
3. If a choice be broken down into two successive choices, the original H should be the weighted sum of the individual values of H . The meaning of this is illustrated in Fig. 6. At the left we have three possibilities $p_1 = \frac{1}{2}, p_2 = \frac{1}{3}, p_3 = \frac{1}{6}$. On the right we first choose between two possibilities each with probability $\frac{1}{2}$, and if the second occurs make another choice with probabilities $\frac{2}{3}, \frac{1}{3}$. The final results have the same probabilities as before. We require, in this special case, that

$$H\left(\frac{1}{2}, \frac{1}{3}, \frac{1}{6}\right) = H\left(\frac{1}{2}, \frac{1}{2}\right) + \frac{1}{2} H\left(\frac{2}{3}, \frac{1}{3}\right).$$

The coefficient $\frac{1}{2}$ is the weighting factor introduced because this second choice only occurs half the time.

Fig. 6.—Decomposition of a choice from three possibilities.

In Appendix 2, the following result is established:

Theorem 2: The only H satisfying the three above assumptions is of the form:

$$H = -K \sum_{i=1}^n p_i \log p_i$$

where K is a positive constant.

This theorem, and the assumptions required for its proof, are in no way necessary for the present theory. It is given chiefly to lend a certain plausibility to some of our later definitions. The real justification of these definitions, however, will reside in their implications.

Quantities, of the form $H = -\sum p_i \log p_i$ (the constant K merely amounts to a choice of a unit of measure) play a central role in information theory as measures of information, choice and uncertainty. The form of H will be recognized as that of **entropy**

Fig. 7.—**Entropy** in the case of two possibilities with probabilities p and $(1-p)$.

as defined in certain formulations of statistical mechanics⁸ where p_i is the probability of a system being in cell i of its phase space.

⁸ See, for example, R. C. Tolman, *Principles of Statistical Mechanics*, Oxford, Clarendon, 1938.

quence of symbols x_i ; and let β be the state of the transducer, which produces, in its output, blocks of symbols y_j . The combined system can be represented by the "product state space" of pairs (α, β) . Two points in the space (α_1, β_1) and (α_2, β_2) , are connected by a line if α_1 can produce an x which changes β_1 to β_2 , and this line is given the probability of that x in this case. The line is labeled with the block of y_1 symbols produced by the transducer. The entropy of the output can be calculated as the weighted sum over the states. If we sum first on β each resulting term is less than or equal to the corresponding term for α , hence the entropy is not increased. If the transducer is non-singular let its output be connected to the inverse transducer. If H'_1, H'_2 and H'_3 are the output entropies of the source, the first and second transducers respectively, then $H'_1 \geq H'_2 \geq H'_3 = H'_1$ and therefore $H'_1 = H'_2$.

Suppose we have a system of constraints on possible sequences of the type which can be represented by a linear graph as in Fig. 2. If probabilities $p_{ij}^{(s)}$ were assigned to the various lines connecting state i to state j this would become a source. There is one particular assignment which maximizes the resulting entropy (see Appendix 4).

Theorem 8: Let the system of constraints considered as a channel have a capacity $C = \log W$. If we assign

$$p_{ij}^{(s)} = \frac{B_j}{B_i} W^{-l_{ij}^{(s)}}$$

where $l_{ij}^{(s)}$ is the duration of the s^{th} symbol leading from state i to state j and the B_i satisfy

$$B_i = \sum_{s,j} B_j W^{-l_{ij}^{(s)}}$$

then H is maximized and equal to C .

By proper assignment of the transition probabilities the entropy of symbols on a channel can be maximized at the channel capacity.

9. The Fundamental Theorem for a Noiseless Channel

We will now justify our interpretation of H as the rate of gen-

erating information by proving that H determines the channel capacity required with most efficient coding.

Theorem 9: Let a source have entropy H (bits per symbol) and a channel have a capacity C (bits per second). Then it is possible to encode the output of the source in such a way as to transmit at the average rate $\frac{C}{H} - \epsilon$ symbols per second over the channel where ϵ is arbitrarily small. It is not possible to transmit at an average rate greater than $\frac{C}{H}$.

The converse part of the theorem, that $\frac{C}{H}$ cannot be exceeded, may be proved by noting that the entropy of the channel input per second is equal to that of the source, since the transmitter must be non-singular, and also this entropy cannot exceed the channel capacity. Hence $H' \leq C$ and the number of symbols per second $= H'/H \leq C/H$.

The first part of the theorem will be proved in two different ways. The first method is to consider the set of all sequences of N symbols produced by the source. For N large we can divide these into two groups, one containing less than $2^{(H+\eta)N}$ members and the second containing less than 2^{RN} members (where R is the logarithm of the number of different symbols) and having a total probability less than μ . As N increases η and μ approach zero. The number of signals of duration T in the channel is greater than $2^{(C-\theta)T}$ with θ small when T is large. If we choose

$$T = \left(\frac{H}{C} + \lambda \right) N$$

then there will be a sufficient number of sequences of channel symbols for the high probability group when N and T are sufficiently large (however small λ) and also some additional ones. The high probability group is coded in an arbitrary one-to-one way into this set. The remaining sequences are represented by larger sequences, starting and ending with one of the sequences not used for the high probability group. This special sequence acts as a start and stop signal for a different code. In between a sufficient time is allowed to give enough different sequences for all the low probability messages. This will require

Entropy and Randomness

- **Entropy** measures the expected “**uncertainly**” (or “surprise”) associated with a random variable.
- Entropy quantifies the “**information content**” and represents a lower bound on the best possible lossless compression.
- Ex: a random fair coin has entropy of **1 bit**.
A **biased** coin has lower entropy than fair coin.
A two-headed coin has **zero entropy**.
- The string 0000000000000000... has **zero entropy**.
- English text has entropy rate of 0.6 to 1.5 bits per letter.

Q: How do you simulate a **fair** coin with a **biased** coin of unknown but **fixed bias**?

A [von Neumann]: Look at **pairs** of flips. **HT** and **TH** both occur with **equal** probability of $p(1-p)$, and ignore **HH** and **TT** pairs.

Entropy and Randomness

- **Information entropy** is an analogue of **thermodynamic entropy** in physics / statistical mechanics, and von Neumann entropy in quantum mechanics.
- **Second law of thermodynamics**: **entropy** of an isolated system **can not decrease over time**.
- Entropy as “**disorder**” or “**chaos**”.
- Entropy as the “**arrow of time**”.
- “**Heat death** of the universe” / black holes
- Quantum computing uses a **quantum information theory** to generalize classical information theory.

Theorem: String compressibility decreases as entropy increases.

Theorem: Most strings are not (losslessly) compressible. ←

Corollary: Most strings are random!

“My greatest concern was what to call it. I thought of calling it ‘information’, but the word was overly used, so I decided to call it ‘**uncertainty**’. When I discussed it with John von Neumann, he had a better idea. Von Neumann told me, ‘You should call it **entropy**, for two reasons. In the first place your uncertainty function has been used in **statistical mechanics** under that name, so it already has a name. In the second place, and more important, **nobody knows what entropy really is**, so in a debate you will always have the advantage.’”

- Claude Shannon on his conversation with John von Neumann regarding what name to give to the “measure of uncertainty” or attenuation in phone-line signals (1949)

Claude E. Shannon Award

— filed under: [awards](#)

The Claude E. Shannon Award of the IT Society has been instituted to honor consistent and profound contributions to the field of information theory. Each Shannon Award winner is expected to present a Shannon Lecture at the following IEEE International Symposium on Information Theory. Transcripts of some of the lectures are available on-line.

Starting for the 2010 Award, the Shannon Award Committee has decided to issue an open call for nominations, preferably using the [nomination form](#). Although anyone may make a nomination, the Committee retains the responsibility of assuring that a suitable slate of candidates is nominated, and may itself generate nominations. Nominations and optional letters of endorsement must be submitted by March 1 to the current President of the IEEE Information Theory Society.

The first Shannon Lecturer was Claude Shannon himself followed by:

- David S. Slepian (1974)
- Robert M. Fano (1976)
- Peter Elias (1977)
- Mark S. Pinsker (1978)
- J. Wolfowitz (1979)
- W. Wesley Peterson (1981)
- [Irving S. Reed](#) (1982)
- [Robert Gallager](#) (1983)
- [Solomon W. Golomb](#) (1985)
- William L. Root (1986)
- James L. Massey (1988)

Robust THP Transceiver Designs

Historical Perspectives

Stephen Kleene (1909-1994)

- Founded recursive function theory
- Pioneered theoretical computer science
- Student of Alonzo Church; was at the Institute for Advanced Study (1940)
- Invented regular expressions
- Kleene star / closure, Kleene algebra, Kleene recursion theorem, Kleene fixed point theorem, Kleene-Rosser paradox

“Kleeneliness is next to Gödeliness”

WHENEVER I LEARN A NEW SKILL I CONCOCT ELABORATE FANTASY SCENARIOS WHERE IT LETS ME SAVE THE DAY.

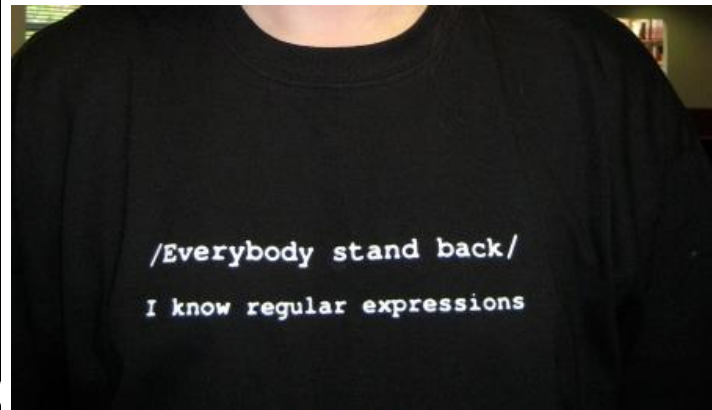

OH NO! THE KILLER MUST HAVE FOLLOWED HER ON VACATION!

BUT TO FIND THEM WE'D HAVE TO SEARCH THROUGH 200 MB OF EMAILS LOOKING FOR SOMETHING FORMATTED LIKE AN ADDRESS!

IT'S HOPELESS!

EVERYBODY STAND BACK.

I KNOW REGULAR EXPRESSIONS.

NATIONAL REGULAR EXPRESSION DAY

a celebration of powerful string manipulation
JUNE 1ST // 2008

Historical Perspectives

Noam Chomsky (1928-)

- Linguist, philosopher, cognitive scientist, political activist, dissident, author
- Father of modern linguistics
- Pioneered formal languages
- Developed generative grammars
Invented context-free grammars
- Defined the Chomsky hierarchy
- Influenced cognitive psychology, philosophy of language and mind
- Chomskyan linguistics, Chomskyan syntax, Chomskyan models
- Critic of U.S. foreign policy
- Most widely cited living scholar
Eighth most-cited source overall!

ANARCHISM

Ur doin it wrong

“...I must admit to taking a copy of **Noam Chomsky's ‘Syntactic Structures’** along with me on my **honeymoon** in 1961 ... Here was a marvelous thing: a **mathematical theory of language** in which I could use as a computer programmer's intuition!”
 - **Don Knuth** on Chomsky's influence

The Adventures of... NOAM CHOMSKY

... and his dog Predicate!

Good news!
I just got an interview on
Nightline!

Don't
screw it
up!

Wait? What do you
mean, "screw it up"?

You know, by
being you!

I..Hey!

If you go on there you're going to
be like, "I'm Noam Chomsky the
Modern Industrial Society must...
big word here, big word there,
U.S. foreign policy this... Blah,
blah, blah..."

I'm not going to compromise my
integrity by contributing to the
numbing of society's intellect!

I need a better way to
get my message out.

Yeah, market
research is saying
that *The Noam
Chomsky Quote of
the Day Calendar* is
giving people
head aches.

What can I do?

There is only
one option!
SELL OUT!

Look Noam, let's be realistic.
You're a downer. People don't want
to hear about how awful things are
all the time!

To do that would be to
undermine the
responsibility of the
Intellectual in our
society! To tell the truth
and expose the lies! If
the problems in the
system are
complicated and the
lies abstruse then I'm
going to say just that! It
is my duty!

OK, fine. So
what's the topic
going to be?

I don't know,
but it's some
sort of panel
discussion,
which I
think will be
very
informative!

Positive spin
Noam, that's the
way to get your
message out!

How can you
possibly put positive
spin on the continuing
decay and directed
destruction of our
basic freedoms?!!

NIGHTLINE

Uh, thank you Professor Chomsky
for that "unique" insight into the hidden
agendas of international trade
organizations. So now, let me pose the
same question to our other
panelist.

Ms. Spears, what is
your opinion of...
fuzzy things?

NIGHTLINE

Noam sez...
*Everything's
Fine!*

The Adventures of... NOAM CHOMSKY

... and his dog Predicate!

By Jeffrey Weston

Predicate, which do you think would be less harmful to the progressive struggle against the corporate power structure in this country?

If I bought 100 grams of plain salted peanuts or 100 grams of plain unsalted peanuts?

I don't care Noam.

Ooooo ooo!

Can I get this cereal?

My Goodness no! It's bad enough that corporations use children as a tool to reach their parent's wallet, but to influence them with subversive cereal themes... That's just disgusting.

Awww, but Noam! It comes with a cool prize!

CAPITALIST CRUNCH

CAPITAL-IZE ME NISTER!

FREE STOCK!
IN EVERY BOX!

PREFERRED

Hey kids!

Now you can own part of the tastiness with one free share of the company in every box!

Capitalist Crunch!

"Taste the Free Market in every bite!
Mmmmm Profitable!"

The Adventures of... NOAM CHOMSKY

... and his dog Predicate!

by Jeffrey Weston

Hey Noam, another documentary film crew is here.

Oh, no. Not again.

So basically we're making a sequel to "Manufacturing Consent."

Is that possible?

Well, our investors say "yes". The university student activist market is very lucrative.

What?

Sure, we can spin off Noam Chomsky T-Shirts, coffee mugs, action figures, waffle irons...

That's disgusting!

Can I get in on that?

Predicate!

You can count me out of this. Fine, we can do this without you.

Here's my investment of \$10,000.

COMING SOON!
TO A UNIVERSITY-
STUDENT-UNION-
BASE-
MENT-MAKE-SHIFT-
SCREENING-ROOM NEAR
YOU!

**MANUFACTURING
CONSENT**
AND OTHER FABULOUS
MERCHANDISE!

The Adventures of... NOAM CHOMSKY

... and his dog Predicate!

by Jeffrey Weston

I can't believe they're going to make a sequel to *Manufacturing Consent* purely to sell merchandise!

Come on! This Noam Chomsky Action Figure is pretty cool! It also corrects your grammar too.

Beep. "It corrects your grammar as well."

It's Win-Win! You get your message out and I, er, they get something in return!

OK, but I want to make sure some conspiring corporate director doesn't dilute my message.

Fine, we'll hire some dorky, idealistic University Student.

I think I'm probably going to regret this.

Beep. "I think I will regret this."

Shut-up

In case you didn't know...

The Adventures of... NOAM CHOMSKY

and his dog Predicate!

by Jeffrey Weston

So Noam, do you see that waffle you're eating as a representation of individual thoughts and freedoms being consumed by the self-serving culture of the powerful elite?

No. It's a waffle.

It's not easy living with Noam Chomsky.

I always hear, "I can't vaccum now", "do your own laundry", "ain't is not a word". It's like doing the dishes is some sort of foreign policy to him.

Hey, did you get that? Foreign policy! Ha!

Why are you interviewing my dog? This documentary is supposed to be about ideas!

Because, I'm far more entertaining.

This is becoming a disaster.

Relax, you're guaranteed at least 2nd billing.

Available only on beautiful VHS!

If we don't believe
in freedom of
expression for
people we despise,
we don't believe in
it at all.

Noam Chomsky

"Propaganda is to a
democracy what the
bludgeon is to a
totalitarian state"
- Noam Chomsky

**COULD CHOMSKY
BE WRONG?**

IDIOT
