We begin with an overview of those areas in the theory of computation that we present in this course. Following that, you'll have a chance to learn and/or review some mathematical concepts that you will need later.

0.1 AUTOMATA, COMPUTABILITY, AND COMPLEXITY

This book focuses on three traditionally central areas of the theory of computation: automata, computability, and complexity. They are linked by the question:

What are the fundamental capabilities and limitations of computers?

This question goes back to the 1930s when mathematical logicians first began to explore the meaning of computation. Technological advances since that time have greatly increased our ability to compute and have brought this question out of the realm of theory into the world of practical concern.

In each of the three areas—automata, computability, and complexity—this question is interpreted differently, and the answers vary according to the interpretation. Following this introductory chapter, we explore each area in a separate part of this book. Here, we introduce these parts in reverse order because starting from the end you can better understand the reason for the beginning.

0.2 MATHEMATICAL NOTIONS AND TERMINOLOGY

As in any mathematical subject, we begin with a discussion of the basic mathematical objects, tools, and notation that we expect to use.

SETS

A set is a group of objects represented as a unit. Sets may contain any type of object, including numbers, symbols, and even other sets. The objects in a set are called its elements or members. Sets may be described formally in several ways. One way is by listing a set's elements inside braces. Thus the set

\{7, 21, 57\}

contains the elements 7, 21, and 57. The symbols ∈ and \∉ denote set membership and nonmembership. We write 7 ∈ \{7, 21, 57\} and 8 \∉ \{7, 21, 57\}. For two sets A and B, we say that A is a subset of B, written A ⊆ B, if every member of
Formal Languages

- **Alphabet**: a *finite* set of symbols
  \[ \Sigma = \{a, b\} \]

- **String**: a *finite* sequence of symbols
  \[ \text{ababbaab} \]

- **Language**: a (possibly \( \infty \)) set of strings
  \[ L = \{a, aa, aaa, \ldots\} \]

- **String length**: number of symbols in it
  \[ |aba| = 3 \]

- **Empty string**: \( \varepsilon \) or \( ^\ast \) \( (|\varepsilon| = 0) \)
  \[ \forall w \; w \cdot \varepsilon = \varepsilon \cdot w = w \]

- **String concatenation**: \( w_1 w_2 \)
  \[ \text{ab \cdot ba = abba} \]

- **Language concatenation**: \( L_1 L_2 = \{w_1 w_2 \mid w_1 \in L_1, w_2 \in L_2\} \)
  \[ = \{1a, 2a, 1b, 2b, \ldots\} \]

- **String exponentiation**: \( w^k = w w \ldots w \) (k times)
  \[ a^3 = aaa \]

- **Language exponentiation**: \( L^k = LL \ldots L \) (k times)
  \[ \{0, 1\}^{32} \]

  \[ LL = L^2 \]
  \[ L^k = LL^{k-1} \]
  \[ L^0 = \{\varepsilon\} \]
Formal Languages

- **String reversal**: $w^R$
  
- **Language reversal**: $L^R = \{w^R \mid w \in L\}$
  
- **Language union**:
  $$L_1 \cup L_2 = \{w \mid w \in L_1 \text{ or } w \in L_2\}$$

- **Language intersection**:
  $$L_1 \cap L_2 = \{w \mid w \in L_1 \text{ and } w \in L_2\}$$

- **Language difference**:
  $$L_1 - L_2 = \{w \mid w \in L_1 \text{ and } w \notin L_2\}$$

- **Kleene closure**: $L^* = L^0 \cup L^1 \cup L^2 \cup \ldots$
  $$L^+ = L^1 \cup L^2 \cup L^3 \cup \ldots$$

- **All finite strings** (over $\Sigma$): $\Sigma^* \subseteq \Sigma^*$ \forall L

**Theorem**: $\Sigma^*$ contains no $\infty$ strings. Only finite strings in $\Sigma^i$
Formal Languages

Language complementation: $L' = \Sigma^* - L$  

“The negation” w.r.t. $\Sigma^*$

Theorem: $(L^*)^* = L^*$

Theorem: $L^+ = LL^*$

• “Trivial” language: $\{\varepsilon\}$

• Empty language: $\emptyset$

Theorem: $\Sigma^*$ is countable, $|\Sigma^*| = |\mathbb{N}|$

Theorem: $2^{\Sigma^*}$ is uncountable.
The theory of computation begins with a question: What is a computer? It is perhaps a silly question, as everyone knows that this thing I type on is a computer. But these real computers are quite complicated—too much so to allow us to set up a manageable mathematical theory of them directly. Instead we use an idealized computer called a computational model. As with any model in science, a computational model may be accurate in some ways but perhaps not in others. Thus we will use several different computational models, depending on the features we want to focus on. We begin with the simplest model, called the finite state machine or finite automaton.

**Finite Automata**

Finite automata are good models for computers with an extremely limited amount of memory. What can a computer do with such a small memory? Many useful things! In fact, we interact with such computers all the time, as they lie at the heart of various electromechanical devices.

The controller for an automatic door is one example of such a device. Often found at supermarket entrances and exits, automatic doors swing open when sensing that a person is approaching. An automatic door has a pad in front to

---

**Definition 1.5**

A finite automaton is a 5-tuple \((Q, \Sigma, \delta, q_0, F)\), where

1. \(Q\) is a finite set called the states,
2. \(\Sigma\) is a finite set called the alphabet,
3. \(\delta: Q \times \Sigma \to Q\) is the transition function,
4. \(q_0 \in Q\) is the start state, and
5. \(F \subseteq Q\) is the set of accept states.

---

1Refer back to page 7 if you are uncertain about the meaning of \(\delta: Q \times \Sigma \to Q\).
2Accept states sometimes are called final states.
Finite Automata

Basic idea: a **FA** is a “**machine**” that changes states while processing symbols, one at a time.

- **Finite** set of states: $Q = \{q_0, q_1, q_3, \ldots, q_k\}$
- **Transition** function: $\delta: Q \times \Sigma \rightarrow Q$
- **Initial** state: $q_0 \in Q$
- **Final** states: $F \subseteq Q$
- **Finite** automaton is $M=(Q, \Sigma, \delta, q_0, F)$

Ex: an FA that accepts all odd-length strings of zeros:

$M=(\{q_0, q_1\}, \{0\}, \{((q_0,0),q_1), ((q_1,0),q_0)\}, q_0, \{q_1\})$
Finite Automata

**FA operation:** consume a string \( w \in \Sigma^* \) one symbol at a time while changing states

**Acceptance:** end up in a **final state**

**Rejection:** anything **else** (including hang-up / crash)

Ex: FA that accepts all strings of form abababab… = (ab)*

\[
M = (\{q_0, q_1\}, \{a, b\}, \{(q_0, a), q_1\}, \{(q_1, b), q_0\}, q_0, \{q_0\})
\]

But \( M \) “crashes” on input string “abba”!

Solution: add dead-end state to fully specify \( M \)

\[
M' = (\{q_0, q_1, q_2\}, \{a, b\}, \{(q_0, a), q_1\}, \{(q_1, b), q_0\},
\{(q_0, b), q_2\}, \{(q_1, a), q_2\}, \{(q_2, a), q_2\}, \{(q_2, b), q_2\}, q_0, \{q_0\})
\]
Finite Automata

Transition function $\delta$ extends from symbols to strings:

$\delta: Q \times \Sigma^* \rightarrow Q$

$\delta(q_0, wx) = \delta(\delta(q_0, w), x)$

where $\delta(q_i, \varepsilon) = q_i$

Language of $M$ is $L(M) = \{ w \in \Sigma^* | \delta(q_0, w) \in F \}$

Definition: language is regular iff it is accepted by some FA.

Theorem: Complementation preserves regularity.

Proof: Invert final and non-final states in fully specified FA.

$L = L(M) = (ab)^*$

$L' = L(M') = b(a+b)^* + (a+b)^*a + (a+b)^*(aa+bb)(a+b)^*$

$M' \text{ "simulates" } M$ and does the opposite!
Problem: design a DFA that accepts all strings over \{a,b\} where any a’s precede any b’s.

Idea: skip over any contiguous a’s, then skip over any b’s, and then accept iff the end is reached.

\[ L = a^*b^* \]

Q: What is the complement of L?
Problem: what is the complement of $L = a^*b^*$?

Idea: write a regular expression and then simplify.

$L' = (a+b)^*b^+(a+b)^*a^+(a+b)^*$

$= (a+b)^*b(a+b)^*a(a+b)^*$

$= (a+b)^*b^+a(a+b)^*$

$= (a+b)^*ba(a+b)^*$

$= a^*b^+a(a+b)^*$
JFLAP Version 7.0
RELEASED August 28, 2009

JFLAP

JFLAP is software for experimenting with formal languages topics including nondeterministic finite automata, nondeterministic pushdown automata, multi-tape Turing machines, several types of grammars, parsing, and FSAs. In addition to constructing and testing examples for these, JFLAP allows one to experiment with construction tools from one form to another, such as converting an NFA to a DFA to a minimal state DFA to a regular expression or regular grammar. Check here for more information on what one can do with JFLAP.

JFLAP News

- *** September 28, 2009 ***
  Note to Mac users. Macs default to Java 1.5 and JFLAP now requires Java 1.6.
- *** August 28, 2009 *** - JFLAP 7.0 released. See below for more details on changes. Get JFLAP

- December 2008 - JFLAP CD by Linz and Rodger with JFLAP exercises that goes along with the Linz book is now available. Click here for info and see the Supplement.

Note, we have worked closely with Linz over the past several years so JFLAP fits nicely with the Linz book. Eventually we hope to publish a textbook with JFLAP integrated in...

- July 2008 - JFLAP now has a wiki where users can discuss the use or modifications of JFLAP, see jflap.wikia.com
- July 2008 - JFLAP now has two listservs. To join, go to lists.duke.edu
  You do not need to be a member of Duke to join the listserv.
  - jflap-announce@duke.edu - for announcements on new releases of JFLAP or new info on the JFLAP web page

Please use this tool!
(to implement some nontrivial FSAs, TMs, PDAs, grammars, etc.)

Nondeterministic states are highlighted.
L = \{a^n b^n c^m : n \geq 0 \}

Context-Free Pumping Lemma

Objective: Find a valid partition that can be pumped.

My Attempts:

Cases:

1. Please select a value for m in Box 1 and press 'Enter'.
2. I have selected w such that |w| = m. It is displayed in Box aaabbbbb.
3. Select decomposition of w into uvxyz.
4. I have selected u to give a contradiction. It is displayed in Box pumped string: aabbbbbccc.
5. Animation

w = aaa b b b ccc

Note: NOT in the language. Please try again.
THE REGULAR OPERATIONS

In the preceding two sections we introduced and defined finite automata and regular languages. We now begin to investigate their properties. Doing so will help develop a toolbox of techniques to use when you design automata to recognize particular languages. The toolbox also will include ways of proving that certain other languages are nonregular (i.e., beyond the capability of finite automata).

In arithmetic, the basic objects are numbers and the tools are operations for manipulating them, such as + and ×. In the theory of computation the objects are languages and the tools include operations specifically designed for manipulating them. We define three operations on languages, called the regular operations, and use them to study properties of the regular languages.

DEFINITION 1.23

Let A and B be languages. We define the regular operations union, concatenation, and star as follows.

- **Union**: \( A \cup B = \{ x \mid x \in A \) or \( x \in B \}. \)
- **Concatenation**: \( A \circ B = \{ xy \mid x \in A \) and \( y \in B \}. \)
- **Star**: \( A^* = \{ x_1x_2 \ldots x_k \mid k \geq 0 \) and each \( x_i \in A \}. \)

You are already familiar with the union operation. It simply takes all the strings in both \( A \) and \( B \) and lumps them together into one language.

The concatenation operation is a little trickier. It attaches a string from \( A \) in front of a string from \( B \) in all possible ways to get the strings in the new language.

The star operation is a bit different from the other two because it applies to a single language rather than to two different languages. That is, the star operation is a **binary operation** instead of a **binary operation**. It works by attaching any number of strings in \( A \) together to get a string in the new language. Because "any number" includes 0 as a possibility, the empty string \( \epsilon \) is always a member of \( A^* \), no matter what \( A \) is.

EXAMPLE 1.24

Let the alphabet \( \Sigma \) be the standard 26 letters \( \{ a, b, \ldots, z \} \). If \( A = \{ \text{good, bad} \} \) and \( B = \{ \text{boy, girl} \} \), then

- \( A \cup B = \{ \text{good, bad, boy, girl} \}, \)
- \( A \circ B = \{ \text{goodboy, goodgirl, badboy, badgirl} \}, \)
- \( A^* = \{ \epsilon, \text{good, bad, goodgood, goodbad, badgood, badbad, goodgoodgood, goodbadgood, goodbadbad,} \ldots \}. \)

Let \( N = \{ 1, 2, 3, \ldots \} \) be the set of natural numbers. When we say that \( N \) is closed under multiplication we mean that, for any \( x \) and \( y \) in \( N \), the product \( x \times y \) also is in \( N \). In contrast \( N \) is not closed under division, as 1 and 2 are in \( N \) but 1/2 is not. Generally speaking, a collection of objects is closed under some operation if applying that operation to members of the collection returns an object still in the collection. We show that the collection of regular languages is closed under all three of the regular operations. In Section 1.3 we show that these are useful tools for manipulating regular languages and understanding the power of finite automata. We begin with the union operation.

THEOREM 1.25

The class of regular languages is closed under the union operation.

In other words, if \( A_1 \) and \( A_2 \) are regular languages, so is \( A_1 \cup A_2 \).

**Proof Idea** We have regular languages \( A_1 \) and \( A_2 \) and want to show that \( A_1 \cup A_2 \) also is regular. Because \( A_1 \) and \( A_2 \) are regular, we know that some finite automaton \( M_1 \) recognizes \( A_1 \) and some finite automaton \( M_2 \) recognizes \( A_2 \). To prove that \( A_1 \cup A_2 \) is regular we demonstrate a finite automaton, call it \( M \), that recognizes \( A_1 \cup A_2 \).

This is a proof by construction. We construct \( M \) from \( M_1 \) and \( M_2 \). Machine \( M \) must accept its input exactly when either \( M_1 \) or \( M_2 \) would accept it in order to recognize the union language. It works by simulating both \( M_1 \) and \( M_2 \) and accepting if either of the simulations accept.

How can we make machine \( M \) simulate \( M_1 \) and \( M_2 \)? Perhaps it first simulates \( M_1 \) on the input and then simulates \( M_2 \) on the input. But we must be careful here! Once the symbols of the input have been read and used to simulate \( M_1 \), we can’t “rewind the input tape” to try the simulation on \( M_2 \). We need another approach.
Finite Automata

Theorem: Intersection preserves regularity.

Proof: ("parallel" simulation):

• Construct all super-states, one per each state pair.

• New super-transition function jumps among super-states, simulating both old transition functions.

• Initial super state contains both old initial states.

• Final super states contains pairs of old final states.

• Resulting DFA accepts $\cap$ of languages of original 2 DFAs (but new size can be the product of their sizes).

Given $M_1=\langle Q_1, \Sigma, \delta_1, q', F_1 \rangle$ and $M_2=\langle Q_2, \Sigma, \delta_2, q'', F_2 \rangle$

construct $M=\langle Q, \Sigma, \delta, q, F \rangle$  \[ Q = Q_1 \times Q_2 \]

$F = F_1 \times F_2$  \[ q = (q', q'') \]

$\delta : Q \times \Sigma \rightarrow Q$  \[ \delta((q_i, q_j), x) = (\delta_1(q_i, x), \delta_2(q_j, x)) \]
Finite Automata

**Theorem:** Union preserves regularity.

Proof: **De Morgan's law:** \( L_1 \cup L_2 = \overline{L_1} \cap \overline{L_2} \)

Or cross-product construction, i.e.,
parallel simulation with \( F = (F_1 \times Q_2) \cup (Q_1 \times F_2) \)

**Theorem:** Set difference preserves regularity.

Proof: **Set identity** \( L_1 - L_2 = L_1 \cap \overline{L_2} \)

Or cross-product construction, i.e.,
parallel simulation with \( F = (F_1 \times (Q_2 - F_2)) \)

**Theorem:** XOR preserves regularity.

Proof: **Set identity** \( L_1 \oplus L_2 = (L_1 \cup L_2) - (L_1 \cap L_2) \)

Or cross-product construction, i.e.,
parallel simulation with \( F = (F_1 \times (Q_2 - F_2)) \cup ((Q_1 - F_1) \times F_2) \)

**Meta-Theorem:** Identity-based proofs are easier!
This concludes the construction of the finite automaton $M$ that recognizes the union of $A_1$ and $A_2$. This construction is fairly simple, and thus its correctness is evident from the strategy described in the proof idea. More complicated constructions require additional discussion to prove correctness. A formal correctness proof for a construction of this type usually proceeds by induction. For an example of a construction proved correct, see the proof of Theorem 1.54. Most of the constructions that you will encounter in this course are fairly simple and so do not require a formal correctness proof.

We have just shown that the union of two regular languages is regular, thereby proving that the class of regular languages is closed under the union operation. We now turn to the concatenation operation and attempt to show that the class of regular languages is closed under that operation, too.

**THEOREM 1.26**

The class of regular languages is closed under the concatenation operation.

In other words, if $A_1$ and $A_2$ are regular languages then so is $A_1 \circ A_2$.

To prove this theorem let’s try something along the lines of the proof of the union case. As before, we can start with finite automata $M_1$ and $M_2$ recognizing the regular languages $A_1$ and $A_2$. But now, instead of constructing automaton $M$ to accept its input if either $M_1$ or $M_2$ accept, it must accept if its input can be broken into two pieces, where $M_1$ accepts the first piece and $M_2$ accepts the second piece. The problem is that $M$ doesn’t know where to break its input (i.e., where the first part ends and the second begins). To solve this problem we introduce a new technique called nondeterminism.

**1.2 NONDETERMINISM**

Nondeterminism is a useful concept that has had great impact on the theory of computation. So far in our discussion, every step of a computation follows in a unique way from the preceding step. When the machine is in a given state and reads the next input symbol, we know what the next state will be—it is determined. We call this **deterministic** computation. In a **nondeterministic** machine, several choices may exist for the next state at any point.

Nondeterminism is a generalization of determinism, so every deterministic finite automaton is automatically a nondeterministic finite automaton. As Figure 1.27 shows, nondeterministic finite automata may have additional features.

**FIGURE 1.28**

Deterministic and nondeterministic computations with an accepting branch

Let’s consider some sample runs of the NFA $N_1$ shown in Figure 1.27. The computation of $N_1$ on input 010110 is depicted in the following figure.

**FIGURE 1.29**

The computation of $N_1$ on input 010110
Finite Automata

Non-determinism: generalizes determinism, where many “next moves” are allowed at each step:

Old \( \delta: Q \times \Sigma \rightarrow Q \)

New \( \delta: 2^Q \times \Sigma \rightarrow 2^Q \)

Computation becomes a “tree”.

Acceptance: \( \exists \) a path from root (start state) to some leaf (a final state)

Ex: non-deterministically accept all strings where the 7th symbol before the end is a “b”:

Input: \( a \ b \ a \ b \ b \ a \ a \ a \) \( \Rightarrow \) Accept!
Finite Automata

Theorem: Non-determinism in FAs doesn’t increase power.

Proof: by simulation:

• Construct all super-states, one per each state subset.

• New super-transition function jumps among super-states, simulating old transition function.

• Initial super state are those containing old initial state.

• Final super states are those containing old final states.

• Resulting DFA accepts the same language as original NFA, but can have exponentially more states.

Q: Why doesn’t this work for PDAs or TMs?
Finite Automata

Note: Powerset construction generalizes the cross-product construction. More general constructions are possible.

EC: Let $\text{HALF}(L) = \{v \mid \exists v, w \in \Sigma^* \; \exists \; |v| = |w| \text{ and } vw \in L\}$
Show that $\text{HALF}$ preserves regularity.

A two way FA can move its head backwards on the input: $\delta : Q \times \Sigma \rightarrow Q \times \{\text{left, right}\}$

EC: Show that two-way FA are not more powerful than ordinary one-way FA.

$\varepsilon$-transitions: $q_i \xrightarrow{\varepsilon} q_j$  

One super-state!

Theorem: $\varepsilon$-transitions don’t increase FA recognition power.
Proof: Simulate $\varepsilon$-transitions FA without using $\varepsilon$-transitions. i.e., consider $\varepsilon$-transitions to be a form of non-determinism.
The movie “Next” (2007) Based on the science fiction story “The Golden Man” by Philip Dick

Premise: a man with the super power of non-determinism!

At any given moment his reality branches into multiple directions, and he can choose the branch that he prefers!

Extra credit!
1. Helps us understand the ubiquitous concept of *parallelism* / concurrency;

2. Illuminates the structure of problems;

3. Can help *save time & effort* by solving intractable problems more efficiently;

4. Enables vast, deep, and general studies of “*completeness*” theories;

5. Helps explain why *verifying* proofs & solutions seems to be easier than *constructing* them;
Why Study Non-determinism?

6. Gave rise to new and novel mathematical approaches, proofs, and analyses;

7. Robustly decouples / abstracts complexity from underlying computational models;

8. Gives disciplined techniques for identifying “hardest” problems / languages;

9. Forged new unifications between computer science, math & logic;

10. Non-determinism is interesting fun, and cool!
Regular Expressions

Regular expressions are defined recursively as follows:

- \( \emptyset \) empty set
- \( \{ \varepsilon \} \) trivial language
- \( \{ x \} \) singleton language

Inductively, if \( R \) and \( S \) are regular expressions, then so are:

- \( (R+S) \) union
- \( RS \) concatenation
- \( R^* \) Kleene closure

Examples:
- \( aa(a+b)^*bb \)
- \( (a+b)^*b(a+b)^*a(a+b)^* \)

Theorem: Any regular expression is accepted by some FA.
First, let's consider again closure under union. Earlier we proved closure under union by simulating deterministically both machines simultaneously via a Cartesian product construction. We now give a new proof to illustrate the technique of nondeterminism. Reviewing the first proof, appearing on page 45, may be worthwhile to see how much easier and more intuitive the new proof is.

**THEOREM 1.45**
The class of regular languages is closed under the union operation.

**PROOF IDEA** We have regular languages $A_1$ and $A_2$ and want to prove that $A_1 \cup A_2$ is regular. The idea is to take two NFAs, $N_1$ and $N_2$ for $A_1$ and $A_2$, and combine them into one new NFA, $N$.

Machine $N$ must accept its input if either $N_1$ or $N_2$ accepts this input. The new machine has a new start state that branches to the start states of the old machines with $\epsilon$ arrows. In this way the new machine nondeterministically guesses which of the two machines accepts the input. If one of them accepts the input, $N$ will accept it, too.

We represent this construction in the following figure. On the left, we indicate the start and accept states of machines $N_1$ and $N_2$ with large circles and some additional states with small circles. On the right, we show how to combine $N_1$ and $N_2$ into $N$ by adding additional transition arrows.

**FIGURE 1.46**
Construction of an NFA $N$ to recognize $A_1 \cup A_2$

**FIGURE 1.50**
Construction of $N$ to recognize $A_1^*$

**PROOF** Let $N_1 = (Q_1, \Sigma, \delta_1, q_1, F_1)$ recognize $A_1$.
Construct $N = (Q, \Sigma, \delta, q_0, F)$ to recognize $A_1^*$.

1. $Q = \{q_0\} \cup Q_1$.
The states of $N$ are the states of $N_1$ plus a new start state.
2. The state $q_0$ is the new start state.
3. $F = \{q_0\} \cup F_1$.
The accept states are the old accept states plus the new start state.
A FA for a regular expressions can be built by composition:

Ex: all strings over \( S = \{a, b\} \) where \( \exists \) a “b” preceding an “a”

\[
(a+b)^*b(a+b)^*a(a+b)^* = (a+b)^*ba(a+b)^*
\]

Why?
FA Minimization

Idea: “Equivalent” states can be merged:

16 states!

merge

3 states!
FA Minimization

Theorem [Hopcroft 1971]: the number N of states in a FA can be minimized within time $O(N \log N)$.

Based on earlier work [Huffman 1954] & [Moore 1956].

Conjecture: Minimizing the number of states in a nondeterministic FA can not be done in polynomial time.

Theorem: Minimizing the number of states in a pushdown automaton (or TM) is undecidable.

Idea: implement a finite automaton minimization tool

• Try to design it to run reasonably efficiently

• Consider also including:
  • A regular-expression-to-FA transformer
  • A non-deterministic-to-deterministic FA converter
FAs and Regular Expressions

**Theorem:** Any FA accepts a language denoted by some RE.

**Proof:** Use “generalized finite automata” where a transition can be a regular expression (not just a symbol), and:

Only 1 **super start state** and 1 (separate) **super final state**.

Each state has transitions to all other states (including itself), except the **super start state**, with no incoming transitions, and the **super final state**, which has no outgoing transitions.
FAs and Regular Expressions

Now reduce the size of the GFA by one state at each step. A transformation step is as follows:

\[ q_i \xrightarrow{P} q_j \]

Such a transformation step is always possible, until the GFA has only two states, the super-start and super-final states:

Label of last remaining transition is the regular expression corresponding to the language of the original FA!

Corollary: FAs and REs denote the same class of languages.
We break this procedure into two parts, using a new type of finite automaton called a \textit{generalized nondeterministic finite automaton}, GNFA. First we show how to convert DFAs into GNFAs, and then GNFAs into regular expressions.

Generalized nondeterministic finite automata are simply nondeterministic finite automata wherein the transition arrows may have any regular expressions as labels, instead of only members of the alphabet or \( \varepsilon \). The GNFA reads blocks of symbols from the input, not necessarily just one symbol at a time as in an ordinary NFA. The GNFA moves along a transition arrow connecting two states by reading a block of symbols from the input, which themselves constitute a string described by the regular expression on that arrow. A GNFA is nondeterministic and so may have several different ways to process the same input string. It accepts its input if its processing can cause the GNFA to be in an accept state at the end of the input. The following figure presents an example of a GNFA.

![A generalized nondeterministic finite automaton](image)

**Figure 1.61**

A generalized nondeterministic finite automaton

For convenience we require that GNFAs always have a special form that meets the following conditions.

- The start state has transition arrows going to every other state but no arrows coming in from any other state.
- There is only a single accept state, and it has arrows coming in from every other state but no arrows going to any other state. Furthermore, the accept state is not the same as the start state.
- Except for the start and accept states, one arrow goes from every state to every other state and also from each state to itself.

We illustrate this approach in Figure 1.63.

![Constructing an equivalent GNFA with one fewer state](image)

**Figure 1.63**

Constructing an equivalent GNFA with one fewer state

In the old machine if \( q_i \) goes to \( q_{\text{trip}} \) with an arrow labeled \( R_1 \), \( q_{\text{trip}} \) goes to itself with an arrow labeled \( R_2 \), \( q_{\text{trip}} \) goes to \( q_j \) with an arrow labeled \( R_3 \), and \( q_i \) goes to \( q_j \) with an arrow labeled \( R_4 \), then in the new machine the arrow from \( q_i \) to \( q_j \) gets the label

\[(R_1)(R_2)^*(R_3) \cup (R_4).\]

We make this change for each arrow going from any state \( q_i \) to any state \( q_j \), including the case where \( q_i = q_j \). The new machine recognizes the original language.

**Proof**

Let's now carry out this idea formally. First, to facilitate the proof, we formally define the new type of automaton introduced. A GNFA is similar to a nondeterministic finite automaton except for the transition function, which has the form

\[\delta: (Q - \{q_{\text{accept}}\}) \times (Q - \{q_{\text{start}}\}) \rightarrow \mathcal{R}.

The symbol \( \mathcal{R} \) is the collection of all regular expressions over the alphabet \( \Sigma \), and \( q_{\text{start}} \) and \( q_{\text{accept}} \) are the start and accept states. If \( \delta(q, q_j) = R \), the arrow from state \( q_i \) to state \( q_j \) has the regular expression \( R \) as its label. The domain of the transition function is \((Q - \{q_{\text{accept}}\}) \times (Q - \{q_{\text{start}}\}) \) because an arrow connects every state to every other state, except that no arrows are coming from \( q_{\text{accept}} \) or going to \( q_{\text{start}} \).
Regular Expressions Identities

- \( R+S = S+R \)
- \( R(ST) = (RS)T \)
- \( R(S+T) = RS+RT \)
- \( (R+S)T = RT+ST \)
- \( \emptyset^* = \varepsilon^* = \varepsilon \)
- \( R+\emptyset = \emptyset+R = R \)
- \( R\varepsilon = \varepsilon R = R \)
- \( R+\varepsilon \neq R \)
- \( (R^*)^* = R^* \)
- \( R\emptyset \neq R \)
- \( (\varepsilon + R)^* = R^* \)
- \( (R^*S^*)^* = (R+S)^* \)
Decidable Finite Automata Problems

Def: A problem is decidable if ∃ an algorithm which can determine (in finite time) the correct answer for any instance.

Given a finite automata $M_1$ and $M_2$:

$Q_1$: Is $L(M_1) = \emptyset$ ?
Hint: graph reachability

$Q_2$: Is $L(M_2)$ infinite ?
Hint: cycle detection

$Q_3$: Is $L(M_1) = L(M_2)$ ?
Hint: consider $L_1 \backslash L_2$ and $L_2 \backslash L_1$
Regular Expression Minimization

**Problem**: find smallest equivalent regular expression
- Decidable (why?)
- Hard: PSPACE-complete

Turing Machine Minimization

**Problem**: find smallest equivalent Turing machine
- Not decidable (why?)
- Not even recognizable (why?)
2

CONTEXT-FREE LANGUAGES

In Chapter 1 we introduced two different, though equivalent, methods of describing languages: finite automata and regular expressions. We showed that many languages can be described in this way but that some simple languages, such as \( \{0^n1^n \mid n \geq 0\} \), cannot.

In this chapter we present context-free grammars, a more powerful method of describing languages. Such grammars can describe certain features that have a recursive structure, which makes them useful in a variety of applications.

Context-free grammars were first used in the study of human languages. One way of understanding the relationship of terms such as noun, verb, and preposition and their respective phrases leads to a natural recursion because noun phrases may appear inside verb phrases and vice versa. Context-free grammars can capture important aspects of these relationships.

An important application of context-free grammars occurs in the specification and compilation of programming languages. A grammar for a programming language often appears as a reference for people trying to learn the language syntax. Designers of compilers and interpreters for programming languages often start by obtaining a grammar for the language. Most compilers and interpreters contain a component called a parser that extracts the meaning of a program prior to generating the compiled code or performing the interpreted execution. A number of methodologies facilitate the construction of a parser once a context-free grammar is available. Some tools even automatically generate the parser from the grammar.

100  CHAPTER 2 / CONTEXT-FREE LANGUAGES

The collection of languages associated with context-free grammars are called the context-free languages. They include all the regular languages and many additional languages. In this chapter, we give a formal definition of context-free grammars and study the properties of context-free languages. We also introduce pushdown automata, a class of machines recognizing the context-free languages. Pushdown automata are useful because they allow us to gain additional insight into the power of context-free grammars.

2.1 CONTEXT-FREE GRAMMARS

The following is an example of a context-free grammar, which we call \( G_1 \).

\[
A \rightarrow 0A1 \\
A \rightarrow B \\
B \rightarrow \#
\]

A grammar consists of a collection of substitution rules, also called productions. Each rule appears as a line in the grammar, comprising a symbol and a string separated by an arrow. The symbol is called a variable. The string consists of variables and other symbols called terminals. The variable symbols often are represented by capital letters. The terminals are analogous to the input alphabet and often are represented by lowercase letters, numbers, or special symbols. One variable is designated as the start variable. It usually occurs on the left-hand side of the topmost rule. For example, grammar \( G_1 \) contains three rules. \( G_1 \)'s variables are \( A \) and \( B \), where \( A \) is the start variable. Its terminals are 0, 1, and \#.

You use a grammar to describe a language by generating each string of that language in the following manner.

1. Write down the start variable. It is the variable on the left-hand side of the top rule, unless specified otherwise.
2. Find a variable that is written down and a rule that starts with that variable. Replace the written down variable with the right-hand side of that rule.
3. Repeat step 2 until no variables remain.

For example, grammar \( G_1 \) generates the string 000111. The sequence of substitutions to obtain a string is called a derivation. A derivation of string 000111 in grammar \( G_1 \) is

\[
A \Rightarrow 0A1 \Rightarrow 00A11 \Rightarrow 000A111 \Rightarrow 000B111 \Rightarrow 000111
\]

You may also represent the same information pictorially with a parse tree. An example of a parse tree is shown in Figure 2.1.
Context-Free Grammars

Basic idea: set of production rules induces a language

- **Finite set of variables:** $V = \{V_1, V_2, \ldots, V_k\}$
- **Finite set of terminals:** $T = \{t_1, t_2, \ldots, t_j\}$
- **Finite set of productions:** $P$
- **Start symbol:** $S$
- **Productions:** $V_i \rightarrow \Delta$ where $V_i \in V$ and $\Delta \in (V \cup T)^*$

Applying $V_i \rightarrow \Delta$ to $\alpha V_i \beta$ yields: $\alpha \Delta \beta$

Note: productions do not depend on “context”
- hence the name “context free”!
Context-Free Grammars

Example:  \[ G: \begin{align*}
S & \rightarrow Sa \\
S & \rightarrow Sb \\
S & \rightarrow \varepsilon
\end{align*} \]

\[ \text{G can be denoted more succinctly as:} \]
\[ G: \quad S \rightarrow Sa \mid Sb \mid \varepsilon \]

Def: A derivation in a grammar G is a sequence of productions applied to the start symbol, ending with a final derived string (of terminals).

Ex:
\[ S \rightarrow Sa \rightarrow \boxed{a} \]
\[ S \rightarrow Sa \rightarrow Sba \rightarrow Saba \rightarrow Saaba \rightarrow \boxed{aaba} \]
\[ S \rightarrow Sa \rightarrow Saa \rightarrow Saaa \rightarrow Sbaaa \rightarrow Sbbaaa \rightarrow \boxed{bbaaa} \]

strings in the language
Context-Free Grammars

**Def:** A string \( w \) is **generated** by a grammar \( G \) if some derivation in \( G \) yields \( w \).

**Example:** \( S \rightarrow Sa \rightarrow Sba \rightarrow Saba \rightarrow Saaba \rightarrow aaba \)

**Def:** The language \( L(G) \) generated by a context-free grammar \( G \) is the set of all strings that \( G \) generates.

**Example:** \( G: S \rightarrow Sa \mid Sb \mid \varepsilon \)
\( \{ \varepsilon, a, aaba, bbaaa, \ldots \} \subseteq L(G) \)
moreover \( \{a,b\}^* \subseteq L(G) \Rightarrow L(G)=\{a,b\}^* \)
i.e., \( L(G)=\Sigma^* \) where \( \Sigma=\{a,b\} \)

**Def:** A language is **context-free** if there exists a context-free grammar that generates it.

**Example:** \( L=\{a,b\}^* \) is context-free (and it is also regular).
Context-Free Grammars

Def: a palindrome reads the same forwards and backwards. e.g., “noon”, “civic”, “level”, “rotor”, “madam”, “kayak”, “radar”, “reviver”, “racecar”, “step on no pets”, etc.

Example: design a context-free grammar that generates all palindromic strings over $\Sigma = \{a,b\}$ i.e., $L = \{w \mid w \in \Sigma^* \text{ and } w = w^R\}$

Idea: generate both ends of $w$ simultaneously, from middle.

$G: \quad S \rightarrow aSa \mid bSb \mid a \mid b \mid \varepsilon$

Derivations:

$S \rightarrow aSa \rightarrow abSba \rightarrow abba$

$S \rightarrow bSb \ S \rightarrow baSab \rightarrow baaSaab \rightarrow baabaab$

$L(G) = \{w \mid w \in \Sigma^* \text{ and } w = w^R\}$
Context-Free Grammars

**Example**: design a context-free grammar for strings representing all well-balanced parenthesis.

**Idea**: create rules for generating nesting & juxtaposition.

\[ G_1: S \rightarrow SS \mid (S) \mid \varepsilon \]

**Ex**: 
\[
S \rightarrow SS \rightarrow (S)(S) \rightarrow (\varepsilon)(\varepsilon) \rightarrow ( ) ( ) \\
S \rightarrow (S) \rightarrow ((S)) \rightarrow ((\varepsilon)) \rightarrow (( )) \\
S \rightarrow (S) \rightarrow (SS) \rightarrow ... \rightarrow (( )(())())
\]

Another grammar:

\[ G_2: S \rightarrow (S)S \mid \varepsilon \]

**Q**: Is \( L(G_1) = L(G_2) \) ?
Example: design a context-free grammar that generates all valid regular expressions.

Idea: embed the regular expression rules in a grammar.

\[
G: \quad S \rightarrow x_i \text{ for each } x_i \in \Sigma_L
\]

\[
S \rightarrow (S) \mid SS \mid S^* \mid S+S
\]

Let \( \Sigma = \{a, b\}^* \)

Derivations:

\[
S \rightarrow S^* \rightarrow (S)^* \rightarrow (S+S)^* \rightarrow (a+b)^*
\]

\[
S \rightarrow SS \rightarrow SSSS \rightarrow abS^*b \rightarrow aba^*a
\]

Theorem: The set of regular expressions is context-free.
Def: A statement /sentence is ambiguous if it has multiple syntactic / semantic interpretations.

Example: “I like dominating people”

Example: \[a - b + c \neq (a-b)+c \]

Example: if \(p\) then if \(q\) then \(S\) else \(T\)

Ambiguity in programs should be avoided!
Ambiguity in Language

I'm a linguist.

I love ambiguity more than most people.

“"I'm glad I'm a man, and so is Lola.”” - Last line of “Lola” song by The Kinks
Ambiguity in Art
Ambiguity in Art
Ambiguity

**Def:** A grammar is *ambiguous* if some string in its language has two non-isomorphic derivations.

**Theorem:** Some context-free grammars are ambiguous.

**Example:**  

$L = \{ \varepsilon \}$  

$G_1: \quad S \rightarrow SS \mid \varepsilon$

Derivation 1: $S \rightarrow \varepsilon$

Derivation 2: $S \rightarrow SS \rightarrow SSS \rightarrow \varepsilon\varepsilon\varepsilon = \varepsilon$

$G_1$ is ambiguous!

$G_2: \quad S \rightarrow \varepsilon$

$L(G_1) = L(G_2) = \{ \varepsilon \}$

$G_2$ is not ambiguous!
Ambiguity

Def: A grammar is **ambiguous** if some string in its language has two non-isomorphic derivations.

Theorem: Some context-free grammars are ambiguous.

Example: \( L = a^* \)

\[ G_3: \quad S \rightarrow SS \mid a \mid \varepsilon \]

Derivation 1: \( S \rightarrow SS \rightarrow aa \)

Derivation 2: \( S \rightarrow SS \rightarrow SSS \rightarrow aa\varepsilon = aa \)

\( G_3 \) is ambiguous!

\[ G_4: \quad S \rightarrow Sa \mid \varepsilon \]

\( L(G_3) = L(G_4) = a^* \)

\( G_4 \) is not ambiguous!
Ambiguity

**Def:** A grammar is *ambiguous* if some string in its language has two non-isomorphic derivations.

**Theorem:** Some context-free grammars are ambiguous.

**Example:** well-balanced parenthesis:

\[ G_5: \quad S \rightarrow SS \mid (S) \mid \varepsilon \]

Derivation 1: \( S \rightarrow (S) \rightarrow (\varepsilon) \rightarrow (\ )\)

Derivation 2: \( S \rightarrow SS \rightarrow (S)S \rightarrow (\varepsilon)\varepsilon \rightarrow (\ )\)

\( G_5 \) is ambiguous!

\[ G_6: \quad S \rightarrow (S)S \mid \varepsilon \]

\( L(G_5) = L(G_6) \)

\( G_6 \) is not ambiguous!
Ambiguity

**Def**: A grammar is **ambiguous** if some string in its language has two non-isomorphic derivations.

**Theorem**: Some context-free grammars are ambiguous. (but non-ambiguous grammars can be found)

**Def**: A context-free language is **inherently ambiguous** if every context-free grammar for it is ambiguous.

**Theorem**: Some context-free languages are inherently ambiguous (i.e., no non-ambiguous CFG exists).

**Ex**: \{a^n b^n c^m d^m | m>0, n>0\} \cup \{a^n b^m c^m d^n | m>0, n>0\} is an inherently ambiguous CF language, and so is \{a^n b^m c^k | n=m or m=k\}
Pushdown Automata

Basic idea: a **pushdown automaton** is a finite automaton that can optionally write to an unbounded **stack**.

- **Finite set of states**: \( Q = \{ q_0, q_1, q_3, \ldots, q_k \} \)
- **Input alphabet**: \( \Sigma \)
- **Stack alphabet**: \( \Gamma \)
- **Transition function**: \( \delta: Q \times (\Sigma \cup \{ \varepsilon \}) \times \Gamma \rightarrow 2^{Q \times \Gamma^*} \)
- **Initial state**: \( q_0 \in Q \)
- **Final states**: \( F \subseteq Q \)

Pushdown automaton is \( M = (Q, \Sigma, \Gamma, \delta, q_0, F) \)

Note: pushdown automata are non-deterministic!
Pushdown Automata

A pushdown automaton can use its stack as an unbounded but access-controlled (last-in/first-out or LIFO) storage.

- A PDA accesses its stack using “push” and “pop”
- Stack & input alphabets may differ.
- Input read head only goes 1-way.
- Acceptance can be by final state or by empty-stack.

Note: a PDA can be made deterministic by restricting its transition function to unique next moves:

$$\delta: Q \times (\Sigma \cup \{\varepsilon\}) \times \Gamma \rightarrow Q \times \Gamma^*$$
Pushdown Automata

**Theorem**: If a language is accepted by some context-free grammar, then it is also accepted by some PDA.

**Theorem**: If a language is accepted by some PDA, then it is also accepted by some context-free grammar.

**Corollary**: A language is context-free iff it is also accepted by some pushdown automaton.

I.E., context-free grammars and PDAs have equivalent “computation power” or “expressiveness” capability.

```
Finite set of variables:  \( V = \{V_1, V_2, \ldots, V_k\} \)
Finite set of terminals:  \( T = \{t_1, t_2, \ldots, t_j\} \)
Finite set of productions:  \( P \)
Start symbol:  \( S \)
Productions:  \( V_i \rightarrow \Delta \) where \( V_i \in V \) and \( \Delta \in (V \cup T)^* \)
Applying \( V_i \rightarrow \Delta \) to \( \alpha V_i \beta \) yields: \( \alpha \Delta \beta \)
```
Closure Properties of CFLs

**Theorem**: The context-free languages are **closed** under union.

Hint: Derive a new grammar for the union.

**Theorem**: The CFLs are **closed** under Kleene closure.

Hint: Derive a new grammar for the Kleene closure.

**Theorem**: The CFLs are **closed** under $\cap$ with regular langs.

Hint: Simulate PDA and FA in parallel.

**Theorem**: The CFLs are **not closed** under intersection.

Hint: Find a counter example.

**Theorem**: The CFLs are **not closed** under complementation.

Hint: Use De Morgan’s law.
Decidable PDA / CFG Problems

Given an arbitrary pushdown automata $M$ (or CFG $G$) the following problems are decidable (i.e., have algorithms):

Q₁: Is $L(M) = \emptyset$ ?
Q₅: Is $L(G) = \emptyset$ ?
Q₂: Is $L(M)$ finite ?
Q₆: Is $L(G)$ finite ?
Q₃: Is $L(M)$ infinite ?
Q₇: Is $L(G)$ infinite ?
Q₄: Is $w \in L(M)$ ?
Q₈: Is $w \in L(G)$ ?
Theorem: the following are undecidable (i.e., there exist no algorithms to answer these questions):

Q: Is PDA M minimal?
Q: Are PDAs M₁ and M₂ equivalent?
Q: Is CFG G minimal?
Q: Is CFG G ambiguous?
Q: Is $L(G₁) = L(G₂)$?
Q: Is $L(G₁) \cap L(G₂) = \emptyset$?
Q: Is CFL L inherently ambiguous?
PDA Enhancements

Theorem: 2-way PDAs are more powerful than 1-way PDAs.

Hint: Find an example non-CFL accepted by a 2-way PDA.

Theorem: 2-stack PDAs are more powerful than 1-stack PDAs.

Hint: Find an example non-CFL accepted by a 2-stack PDA.

Theorem: 1-queue PDAs are more powerful than 1-stack PDAs.

Hint: Find an example non-CFL accepted by a 1-queue PDA.

Theorem: 2-head PDAs are more powerful than 1-head PDAs.

Hint: Find an example non-CFL accepted by a 2-head PDA.

Theorem: Non-determinism increases the power of PDAs.

Hint: Find a CFL not accepted by any deterministic PDA.
1.4 NONREGULAR LANGUAGES

To understand the power of finite automata you must also understand their limitations. In this section we show how to prove that certain languages cannot be recognized by any finite automaton.

Let's take the language $B = \{0^n1^n | n \geq 0 \}$. If we attempt to find a DFA that recognizes $B$, we discover that the machine seems to need to remember how many 0s have been seen so far as it reads the input. Because the number of 0s isn't limited, the machine will have to keep track of an unlimited number of possibilities. But it cannot do so with any finite number of states.

Next, we present a method for proving that languages such as $B$ are not regular. Doesn't the argument already given prove nonregularity because the number of 0s is unlimited? It does not. Just because the language appears to require unbounded memory doesn't mean that it is necessarily so. It does happen to be true for the language $B$, but other languages seem to require an unlimited number of possibilities, yet actually they are regular. For example, consider two languages over the alphabet $\Sigma = \{0,1\}$:

- $C = \{ w | w \text{ has an equal number of 0s and 1s} \}$, and
- $D = \{ w | w \text{ has an equal number of occurrences of 01 and 10 as substrings} \}$.

At first glance a recognizing machine appears to need to count in each case, and therefore neither language appears to be regular. As expected, $C$ is not regular, but surprisingly $D$ is regular. Thus our intuition can sometimes lead us astray, which is why we need mathematical proofs for certainty. In this section we show how to prove that certain languages are not regular.

THE PUMPING LEMMA FOR REGULAR LANGUAGES

Our technique for proving nonregularity stems from a theorem about regular languages, traditionally called the pumping lemma. This theorem states that all regular languages have a special property. If we can show that a language does not have this property, we are guaranteed that it is not regular. The property states that all strings in the language can be "pumped" if they are at least as long as a certain special value, called the pumping length. That means each such string contains a section that can be repeated any number of times with the resulting string remaining in the language.

---

Let's see why this division of $s$ satisfies the three conditions. Suppose that we run $M$ on input $xyyz$. We know that $x$ takes $M$ from $q_0$ to $q_1$, and then the first $y$ takes it from $q_0$ back to $q_0$, as does the second $y$, and then $z$ takes it to $q_{13}$. With $q_{13}$ being an accept state, $M$ accepts input $xyyz$. Similarly, it will accept $xy^iz$ for any $i > 0$. For the case $i = 0$, $xy^0z = xz$, which is accepted for similar reasons. That establishes condition 1.

Checking condition 2, we see that $|y| > 0$, as it was the part of $s$ that occurred between two different occurrences of state $q_0$.

In order to get condition 3, we make sure that $q_0$ is the first repetition in the sequence. By the pigeonhole principle, the first $p+1$ states in the sequence must contain a repetition. Therefore $|xy| \leq p$.

**Proof** Let $M = (Q, \Sigma, \delta, q_0, F)$ be a DFA recognizing $A$ and $p$ be the number of states of $M$.

Let $s = s_1s_2 \cdots s_n$ be a string in $A$ of length $n$, where $n \geq p$. Let $r_1, \ldots, r_{p+1}$ be the sequence of states that $M$ enters while processing $s$, so $r_{i+1} = \delta(r_i, s_i)$ for $1 \leq i \leq n$. This sequence has length $n+1$, which is at least $p+1$. Among the first $p+1$ elements in the sequence, two must be the same state, by the pigeonhole principle. We call the first of these $r_j$ and the second $r_l$. Because $r_l$ occurs among the first $p+1$ places in a sequence starting at $r_1$, we have $l \leq p+1$. Now let $x = s_1 \cdots s_{j-1}$, $y = s_j \cdots s_{l-1}$, and $z = s_l \cdots s_{n}$.

As $x$ takes $M$ from $r_1$ to $r_j$, $y$ takes $M$ from $r_j$ to $r_j$, and $z$ takes $M$ from $r_j$ to $r_{n+1}$, which is an accept state, $M$ must accept $xy^iz$ for $i \geq 0$. We know that $j \neq l$, so $|y| > 0$; and $l \leq p+1$, so $|xy| \leq p$. Thus we have satisfied all conditions of the pumping lemma.
Context-Free Grammars

**Def:** A language is context-free if it is generated by some context-free grammar.

**Theorem:** All regular languages are context-free.

Proof idea: construct a grammar that “simulates” a DFA, where variables correspond to states, etc.

**Theorem:** Some context-free languages are not regular.

**Ex:** \{0^n1^n \mid n > 0\}

Proof by “pumping” argument: long strings in a regular language contain a **pumpable** substring.

\[ \exists N \in \mathbb{N} \ \forall z \in L, |z| \geq N \ \exists u, v, w \in \Sigma^* \ \exists z = uvw, |uv| \leq N, |v| \geq 1, uv^i w \in L \ \forall i \geq 0. \]

**Theorem:** Some languages are not context-free.

**Ex:** \{0^n1^n1^n \mid n > 0\}
Turing Machines

Basic idea: a **Turing machine** is a finite automaton that can optionally write to an unbounded tape.

- **Finite set of states:** \( Q = \{ q_0, q_1, q_3, \ldots, q_k \} \)
- **Tape alphabet:** \( \Gamma \)
- **Blank symbol:** \( \beta \in \Gamma \)
- **Input alphabet:** \( \Sigma \subseteq \Gamma - \{ \beta \} \)
- **Transition function:** \( \delta: (Q - F) \times \Gamma \rightarrow Q \times \Gamma \times \{ L, R \} \)
- **Initial state:** \( q_0 \in Q \)
- **Final states:** \( F \subseteq Q \)

**Turing machine** is \( M=(Q, \Gamma, \beta, \Sigma, \delta, q_0, F) \)
Turing Machines

A Turing machine can use its tape as an unbounded storage but reads / writes only at head position.

- Initially the entire tape is blank, except the input portion
- Read / write head goes left / right with each transition
- Input string acceptance is by final state(s)
- A Turing machine is usually deterministic
Larger alphabet:

old: \( \Sigma=\{0,1\} \)  
new: \( \Sigma' =\{a,b,c,d\} \)

Idea: Encode larger alphabet using smaller one.

Encoding example: \( a=00, b=01, c=10, d=11 \)
Turing Machine “Enhancements”

Double-sided infinite tape:

Idea: Fold into a normal single-sided infinite tape

old: $\delta$

new: $\delta'$

Dovetailing!
Multiple heads:

Idea: Mark heads locations on tape and simulate

Modified $\delta'$ processes each “virtual” head independently:
- Each move of $\delta$ is simulated by a long scan & update
- $\delta'$ updates & marks all “virtual” head positions
Multiple tapes:

<table>
<thead>
<tr>
<th>1</th>
<th>1</th>
<th>0</th>
<th>1</th>
<th>0</th>
<th>1</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Idea: Interlace multiple tapes into a single tape

Modified $\delta'$ processes each “virtual” tape independently:

- Each move of $\delta$ is simulated by a long scan & update
- $\delta'$ updates R/W head positions on all “virtual tapes”
Turing Machine “Enhancements”

Two-dimensional tape:

```
 1 1 0 1 0 1
 0 1 1 0 1
 1 0 1 1 0 0
```

Idea: Flatten 2-D tape into a 1-D tape

```
$   
$   
$ ...
```

Modified 1-D δ' simulates the original 2-D δ:

- Left/right δ moves: δ' moves horizontally
- Up/down δ moves: δ' jumps between tape sections

This is how compilers implement 2D arrays!
Turing Machine “Enhancements”

Non-determinism:

Idea: Parallel-simulate non-deterministic threads

Modified deterministic δ' simulates the original ND δ:
- Each ND move by δ spawns another independent “thread”
- All current threads are simulated “in parallel”
Turing Machine “Enhancements”

Combinations:

Idea: “Enhancements” are independent (and commutative with respect to preserving the language recognized).

Theorem: Combinations of “enhancements” do not increase the power of Turing machines.
Def: A language is **Turing-decidable** iff it is exactly the set of strings accepted by some *always-halting* TM.

Note: M must **always halt** on every input.
Turing-Recognizable vs. -Decidable

Def: A language is Turing-recognizable iff it is exactly the set of strings accepted by some Turing machine.

Note: M can run forever on an input, which is implicitly a reject (since it is not an accept).
Recognition vs. Enumeration

Def: “Decidable” means “Turing-decidable”
“Recognizable” means “Turing-recognizable”

Theorem: Every decidable language is also recognizable.

Theorem: Some recognizable languages are not decidable.

Ex: The halting problem is recognizable but not decidable.

Note: Decidability is a special case of recognizability.

Note: It is easier to recognize than to decide.
Famous Deciders

“I'm the decider, and I decide what is best.”

“A wrong decision is better than indecision.”
Def: An “enumerator” Turing machine for a language L prints out precisely all strings of L on its output tape.

Note: The order of enumeration may be arbitrary.

Theorem: If a language is decidable, it can be enumerated in lexicographic order by some Turing machine.

Theorem: If a language can be enumerated in lexicographic order by some TM, it is decidable.
Recognition and Enumeration

Def: An “enumerator” Turing machine for a language L prints out precisely all strings of L on its output tape.

Note: The order of enumeration may be arbitrary.

Theorem: If a language is recognizable, then it can be enumerated by some Turing machine.

Theorem: If a language can be enumerated by some TM, then it is recognizable.

Decidability

Def: A language is Turing-decidable iff it is exactly the set of strings accepted by some always-halting TM.

Theorem: The finite languages are decidable.

Theorem: The regular languages are decidable.

Theorem: The context-free languages are decidable.
A “Simple” Example

Let \( S = \{ x^3 + y^3 + z^3 \mid x, y, z \in \mathbb{Z} \} \)

Q: Is \( S \) infinite?
A: Yes, since \( S \) contains all cubes.

Q: Is \( S \) Turing-recognizable?
A: Yes, since dovetailing TM can enumerate \( S \).

Q: Is \( S \) Turing-decidable?
A: Unknown!

Q: Is \( 29 \in S? \)
A: Yes, since \( 3^3 + 1^3 + 1^3 = 29 \)

Q: Is \( 30 \in S? \)
A: Yes, since \( (2220422932)^3 + (-2218888517)^3 + (-283059965)^3 = 30 \)

Q: Is \( 33 \in S? \)
A: Unknown!

Theorem [Matiyasevich, 1970]: Hilbert’s 10th problem (1900), namely of determining whether a given Diophantine (i.e., multi-variable polynomial) equation has any integer solutions, is not decidable.
Closure Properties of Decidable Languages

Theorem: The decidable languages are closed under union.
   Hint: use simulation.

Theorem: The decidable languages are closed under \( \cap \).
   Hint: use simulation.

Theorem: The decidable langs are closed under complement.
   Hint: simulate and negate.

Theorem: The decidable langs are closed under concatenation.
   Hint: guess-factor string and simulate.

Theorem: The decidable langs are closed under Kleene star.
   Hint: guess-factor string and simulate.
Closure Properties of Recognizable Languages

**Theorem**: The recognizable languages are closed under union.

Hint: use simulation.

**Theorem**: The recognizable languages are closed under \( \cap \).

Hint: use simulation.

**Theorem**: The recognizable langs are not closed under \( \text{compl} \).

Hint: reduction from halting problem.

**Theorem**: The recognizable langs are closed under concat.

Hint: guess-factor string and simulate.

**Theorem**: The recognizable langs are closed under Kleene star.

Hint: guess-factor string and simulate.
Reducibilities

Def: A language A is reducible to a language B if there exists a computable function/map \( f: \Sigma^* \rightarrow \Sigma^* \) where
\[
\forall w \quad w \in A \iff f(w) \in B
\]

Note: \( f \) is called a "reduction" of A to B

Denotation: \( A \leq B \)

Intuitively, A is "no harder" than B
Reducibilities

**Def:** A language $A$ is **reducible** to a language $B$ if

\[ \exists \text{computable function/map } f: \Sigma^* \rightarrow \Sigma^* \text{ where} \]

\[ \forall w \quad w \in A \iff f(w) \in B \]

**Theorem:** If $A \leq B$ and $B$ is decidable then $A$ is decidable.

**Theorem:** If $A \leq B$ and $A$ is undecidable then $B$ is undecidable.

**Note:** be very careful about the mapping direction!
Reduction Example 1

Def: Let $H_\varepsilon$ be the halting problem for TMs running on $w=\varepsilon$.

“Does TM $M$ halt on $\varepsilon$?”

$H_\varepsilon = \{ <M> \in \Sigma^*| M(\varepsilon) \text{ halts} \}$

Theorem: $H_\varepsilon$ is not decidable.

Proof: Reduction from the Halting Problem $H$:

Given an arbitrary TM $M$ and input $w$, construct new TM $M'$ that if it ran on input $x$, it would:

1. Overwrite $x$ with the fixed $w$ on tape;
2. Simulate $M$ on the fixed input $w$;
3. Accept $\iff M$ accepts $w$.

Note: $M'$ is not run!

Note: $M'$ halts on $\varepsilon$ (and on any $x \in \Sigma^*$) $\iff M$ halts on $w$.

A decider (oracle) for $H_\varepsilon$ can thus be used to decide $H$!

Since $H$ is undecidable, $H_\varepsilon$ must be undecidable also.
Proof: Reduction from the Halting Problem H:
Given an arbitrary TM $M$ and input $w$, construct new TM $M'$
that if it ran on input $x$, it would:

1. Overwrite $x$ with the fixed $w$ on tape;
2. Simulate $M$ on the fixed input $w$;
3. Accept $\iff M$ accepts $w$.

Note: $M'$ is not run!

Note: $M'$ halts on every $x \in \Sigma^* \iff M$ halts on $w$.

A decider (oracle) for $L_\emptyset$ can thus be used to decide H!
Since H is undecidable, $L_\emptyset$ must be undecidable also.
Definition: Let $L_{\text{reg}}$ be the regularity problem for TMs.

"Is $L(M)$ regular?" $L_{\text{reg}} = \{ <M> \in \sum^* | L(M) \text{ is regular} \}$

Theorem: $L_{\text{reg}}$ is not decidable.

Proof: Reduction from the Halting Problem $H$:

Given an arbitrary TM $M$ and input $w$, construct new TM $M'$ that if it ran on input $x$, it would:

1. Accept if $x \in 0^n1^n$
2. Overwrite $x$ with the fixed $w$ on tape;
3. Simulate $M$ on the fixed input $w$;
4. Accept $\iff M$ accepts $w$.

Note: $M'$ is not run!

Note: $L(M') = \sum^* \iff M$ halts on $w$

$$L(M') = 0^n1^n \iff M \text{ does not halt on } w$$

A decider (oracle) for $L_{\text{reg}}$ can thus be used to decide $H$!
Rice’s Theorem

**Def:** Let a “property” P be a set of recognizable languages.

**Ex:**

\[ P_1 = \{L \mid L \text{ is a decidable language}\} \]

\[ P_2 = \{L \mid L \text{ is a context-free language}\} \]

\[ P_3 = \{L \mid L = L^*\} \]

\[ P_4 = \{\{\varepsilon\}\} \]

\[ P_5 = \emptyset \]

\[ P_6 = \{L \mid L \text{ is a recognizable language}\} \]

L is said to “have property P” iff \( L \in P \)

**Ex:**

\( (a+b)^* \) has property \( P_1, P_2, P_3 \) & \( P_6 \) but not \( P_4 \) or \( P_5 \)

\( \{ww^R\} \) has property \( P_1, P_2, \) & \( P_6 \) but not \( P_3, P_4 \) or \( P_5 \)

**Def:** A property is “trivial” iff it is empty or it contains all recognizable languages.
Rice’s Theorem

Theorem: The two trivial properties are decidable.

Proof:

\[ P_{\text{none}} = \emptyset \quad x \rightarrow \begin{cases} \text{Ignore } x \\ \text{Say “no”} \\ \text{Stop} \end{cases} \quad M_{\text{none}} \rightarrow \text{no} \]

\[ P_{\text{all}} = \{ L \mid L \text{ is a recognizable language} \} \]

\[ M_{\text{all}} \text{ decides } P_{\text{all}} \quad x \rightarrow \begin{cases} \text{Ignore } x \\ \text{Say “yes”} \\ \text{Stop} \end{cases} \quad M_{\text{all}} \rightarrow \text{yes} \]

Q: What other properties (other than \( P_{\text{none}} \) and \( P_{\text{all}} \)) are decidable?

A: None!
Rice’s Theorem

Theorem [Rice, 1951]: All non-trivial properties of the Turing-recognizable languages are not decidable.

Proof: Let $P$ be a non-trivial property.

Without loss of generality assume $\emptyset \notin P$, otherwise substitute $P$’s complement for $P$ in the remainder of this proof.

Select $L \in P$ (note that $L \neq \emptyset$ since $\emptyset \notin P$), and let $M_L$ recognize $L$ (i.e., $L(M_L) = L \neq \emptyset$).

Assume (towards contradiction) that $\exists$ some TM $M_P$ which decides property $P$:

Note: $x$ can be e.g., a TM description.
Rice’s Theorem

Reduction strategy: use $M_p$ to “solve” the **halting problem**.

Recall that $L \in P$, and let $M_L$ recognize $L$ (i.e., $L(M_L) = L \neq \emptyset$). Given an arbitrary TM $M$ & string $w$, construct $M'$:

What is the language of $M'$?
$L(M')$ is either $\emptyset$ or $L(M_L) = L$
If $M$ halts on $w$ then $L(M') = L(M_L) = L$
If $M$ does not halt on $w$ then $L(M') = \emptyset$ since $M_L$ never starts

$\implies$ $M$ halts on $w$ iff $L(M')$ has property $P$

“Oracle” $M_p$ can determine if $L(M')$ has property $P$, and thereby “solve” the halting problem, a contradiction!
Rice’s Theorem

**Corollary**: The following questions are not decidable: given a TM, is its language \( L \):

- Empty?
- Finite?
- Infinite?
- Co-finite?
- Regular?
- Context-free?
- Inherently ambiguous?
- Decidable?
- \( L = \Sigma^* \) ?
- \( L \) contains an odd string?
- \( L \) contains a palindrome?
- \( L = \{ \text{Hello, World} \} \) ?
- \( L \) is NP-complete?
- \( L \) is in PSPACE?

**Warning**: Rice’s theorem applies to properties (i.e., sets of languages), not (directly to) TM’s or other object types!
Context-Sensitive Grammars

Problem: design a context-sensitive grammar to accept the (non-context-free) language \( \{ 1^n \$ 1^{2n} | n \geq 1 \} \)

Idea: generate \( n \) 1’s to the left & to the right of \( \$ \); then double \( n \) times the # of 1’s on the right.

\[
\begin{align*}
S & \rightarrow 1N D 1E \quad /* Base case; E marks end-of-string */ \\
N & \rightarrow 1N D \mid \$ \quad /* Loop: n 1’s and n D’s; end with $ */ \\
D1 & \rightarrow 11D \quad /* Each D doubles the 1’s on right */ \\
DE & \rightarrow E \quad /* The E “cancels” out the D’s */ \\
E & \rightarrow \varepsilon \quad /* Process ends when the E vanishes */
\end{align*}
\]
Example: Generating strings in \( \{ 1^n1^{2n} \mid n \geq 1 \} \)

\[
S \to 1ND1E \\
N \to 1ND | $ \\
D1 \to 11D \\
E \to \varepsilon \\
DE \to E
\]

\[
S \to 1\text{ND1E} \\
\to 11\text{ND1E} \\
\to 11\text{ND11DE} \\
\to 111\text{ND11DE} \\
\to 111\text{ND11D1DE} \\
\to 111\text{N11D1D1DE} \\
\to 111\text{$111D1D1$E} \\
\to 111\text{$111D1D1$E} \\
\to 111\text{$111D1D1$E}
\]

\[
\rightarrow 111111DD1E \\
\rightarrow 111111D11DE \\
\rightarrow 111111D11DE \\
\rightarrow 111111111D1DE \\
\rightarrow 111111111D1DE \\
\rightarrow 1111111111DE \\
\rightarrow 1111111111E \\
\rightarrow 1111111111\varepsilon \\
= 1^31^8 = 1^31^{2^3}
\]
\[ \frac{H(-ib) + 2}{\Psi - i\hbar^2} + \frac{m^2}{B} \left( \frac{T_2}{E} \left( \frac{P - q}{K} \right) \sum_{k \in \mathbb{Z}} \right) = 0 \]

“But this is the simplified version for the general public.”
