Query Cost Estimation

CS 4750
Database Systems

[A. Silberschatz, H. F. Korth, S. Sudarshan, Database System Concepts, Ch.15]
[C.M. Ricardo, S.D. Urban, "Databases Illuminated, Ch.13]

Review 1: SQL and RA

Consider the following schema statements.

```
student(ID, name, dept_name, tot_cred)
takes(ID, course_ID, sec_id, semester, year, grade)
```

Find IDs and names of all students who have taken more than 3 courses

1. Write SQL query
2. Draw an RA plan

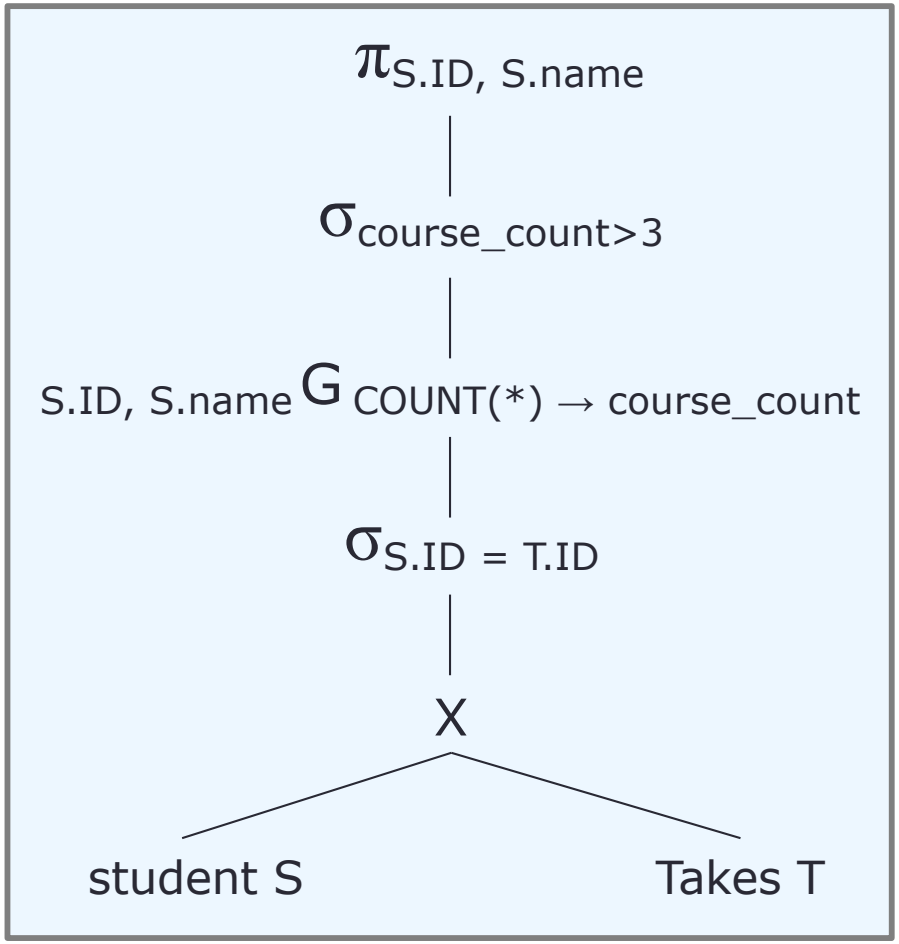
Review 1: SQL and RA (solution)

```
student(ID, name, dept_name, tot_cred)
takes(ID, course_ID, sec_id, semester, year, grade)
```

Find IDs and names of all students who have taken more than 3 courses

```
SELECT DISTINCT S.ID, S.name
FROM student S, takes T
WHERE S.ID = T.ID
GROUP BY S.ID, S.name
HAVING COUNT(*) > 3
```

$$\pi_{S.ID,\ S.\ name}\ (\ \sigma_{\ course\_count\ >3}\ (\ S.ID,\ S.name\ G_{COUNT(*)\ \rightarrow\ course\_count}\ (\ \sigma_{S.ID\ =\ T.ID}\ (\ \rho_{(S)}\ student\ \times\ \rho_{(T)}\ takes\ )\ )\ )\ )$$



Review 2: SQL and RA

Consider the following schema statements.

```
emp(empno, ename, job, mgr, hiredate, salary, comm, deptno)
dept(deptno, dname, loc)
```

Find the names of departments where more than three employees are working

1. Write SQL query
2. Draw an RA plan

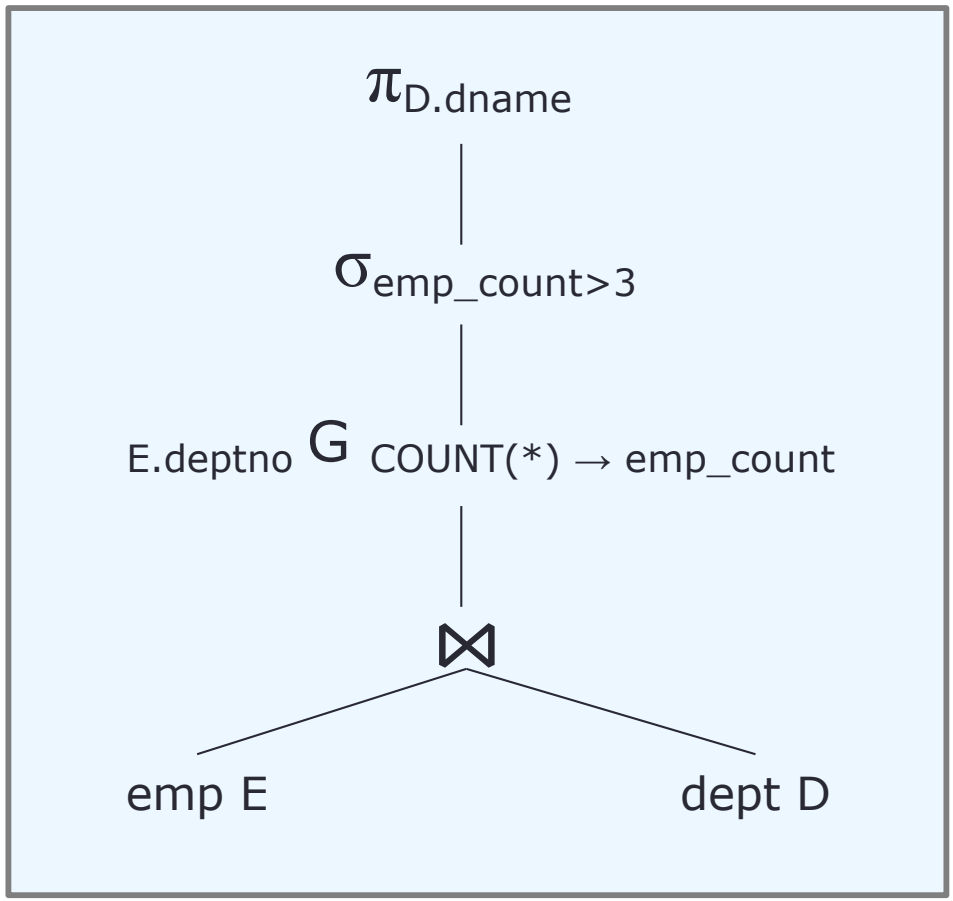
Review 2: SQL and RA (solution 1)

```
emp(empno, ename, job, mgr, hiredate, salary, comm, deptno)
dept(deptno, dname, loc)
```

Find the names of departments where more than three employees are working

```
SELECT D.dname
FROM emp E
    NATURAL JOIN dept D
GROUP BY E.deptno
HAVING COUNT(*)>3;
```

$$\pi_{D.dname}(\sigma_{emp\_count>3}(\ {}_{E.deptno}G_{COUNT(*) \rightarrow emp\_count}(\ \rho_{(E)}emp \bowtie \rho_{(D)}dept\ )\ )\ )$$



Review 2: SQL and RA (solution 2)

```
emp(empno, ename, job, mgr, hiredate, salary, comm, deptno)
dept(deptno, dname, loc)
```

Find the names of departments where more than three employees are working

Can you think of another solution?

Review 2: SQL and RA (solution 2)

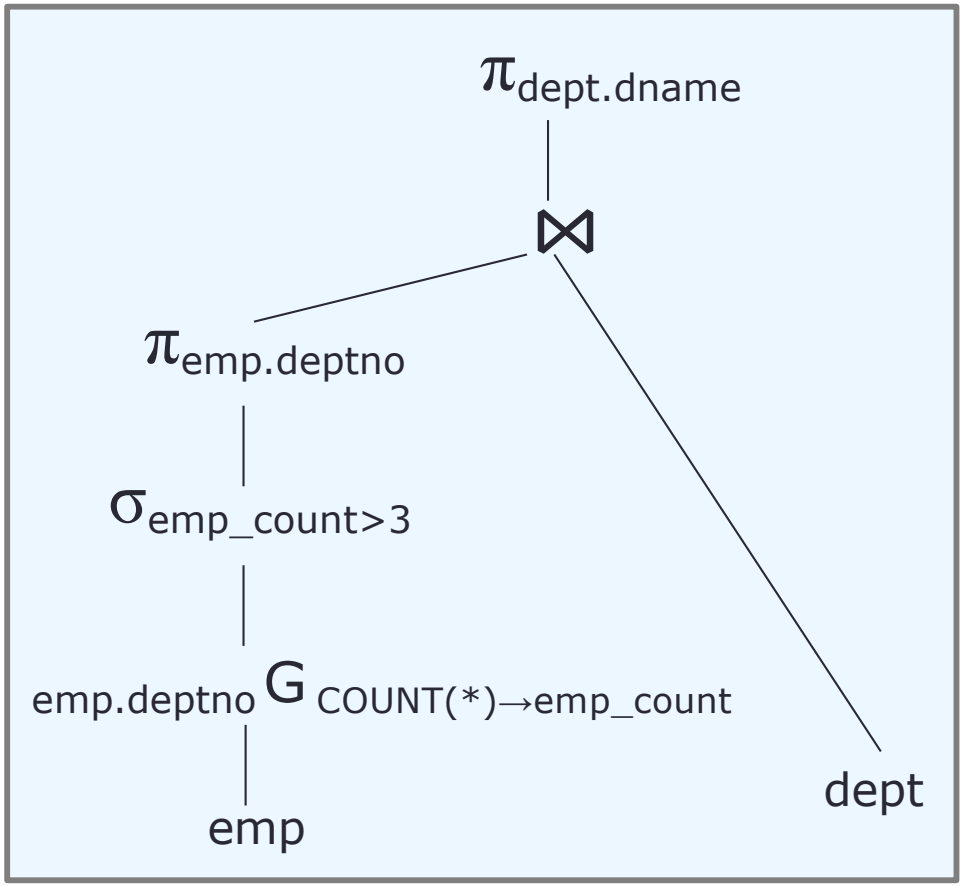
emp(<u>empno</u>, ename, job, mgr, hiredate, salary, comm, deptno)
dept(<u>deptno</u>, dname, loc)

Find the names of departments where more than three employees are working

Another solution:

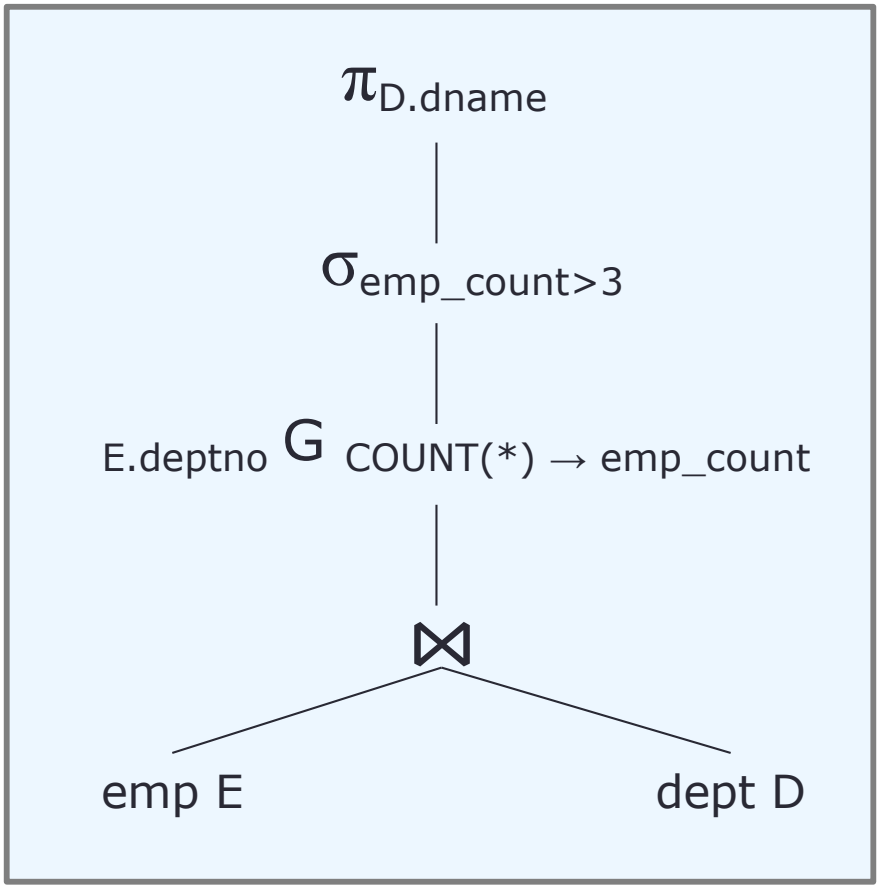
```
SELECT dept.dname
FROM (
    SELECT deptno
    FROM emp
    GROUP BY deptno
    HAVING COUNT(*)>3 )
NATURAL JOIN dept
```

$\pi_{dept.dname}$ (
$\pi_{emp.deptno}$ ($\sigma_{emp\_count>3}$ (
$_{emp.deptno}\mathcal{G}_{COUNT(*) \rightarrow emp\_count}$ (emp)))
$\bowtie$ dept)

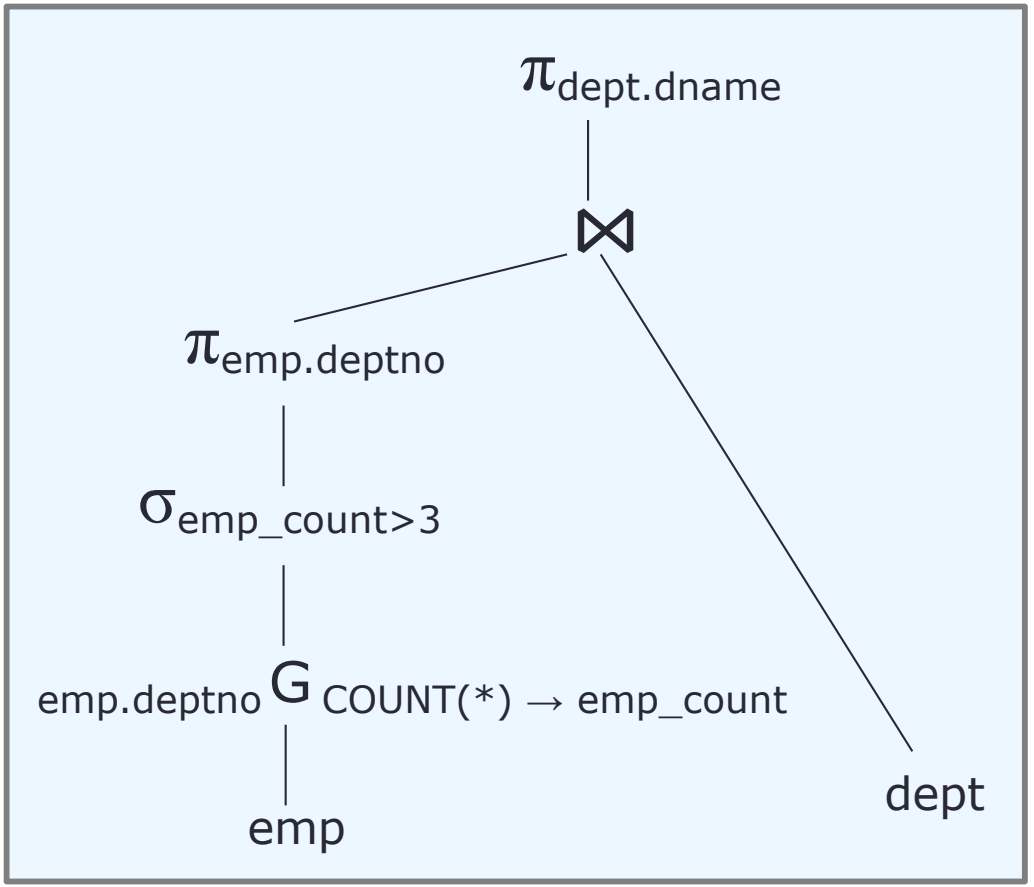


Review 2: SQL and RA (solutions 1 vs. 2)

Can you verify equivalence?



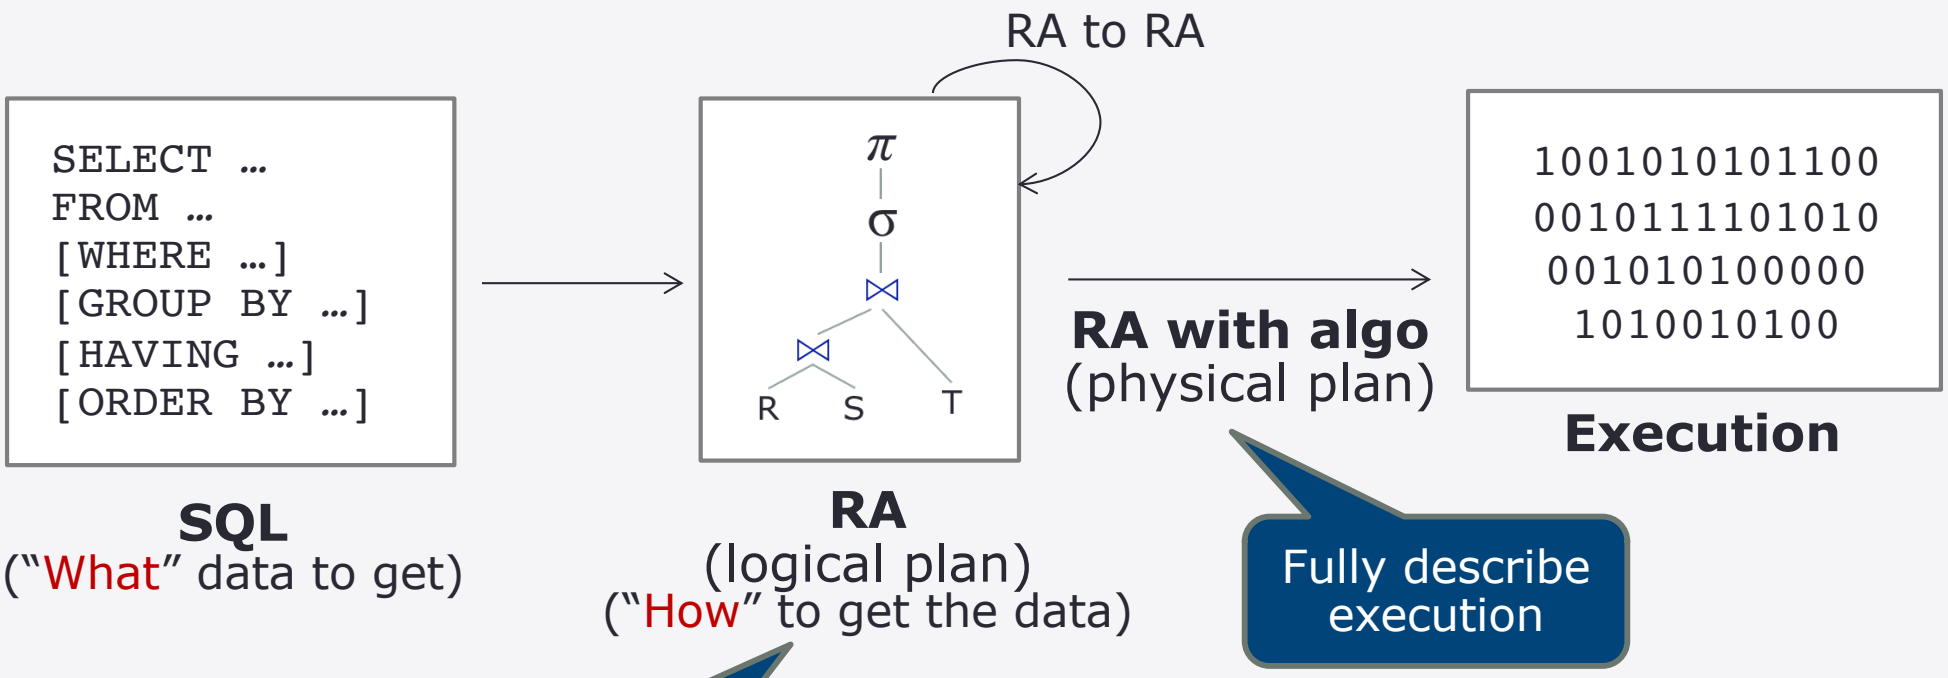
solution 1



solution 2

What's the Point of RA?

RDBMS

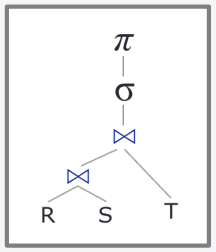


Overview: Query Processing

RDBMS

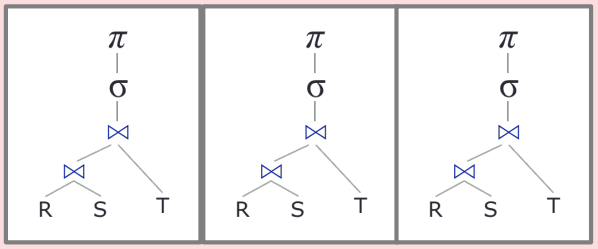
```
SELECT …
FROM …
[WHERE …]
[GROUP BY …]
[HAVING …]
[ORDER BY …]
```

SQL



RA
(logical plan)

"Plan enumeration"



…

RA
(Set of equivalent logical plans)

Set of equivalent
Physical plans

Least cost plan

CS4750 considers
"Cardinality estimation"

```
1001010101100
0010111101010
001010100000
1010010100
```

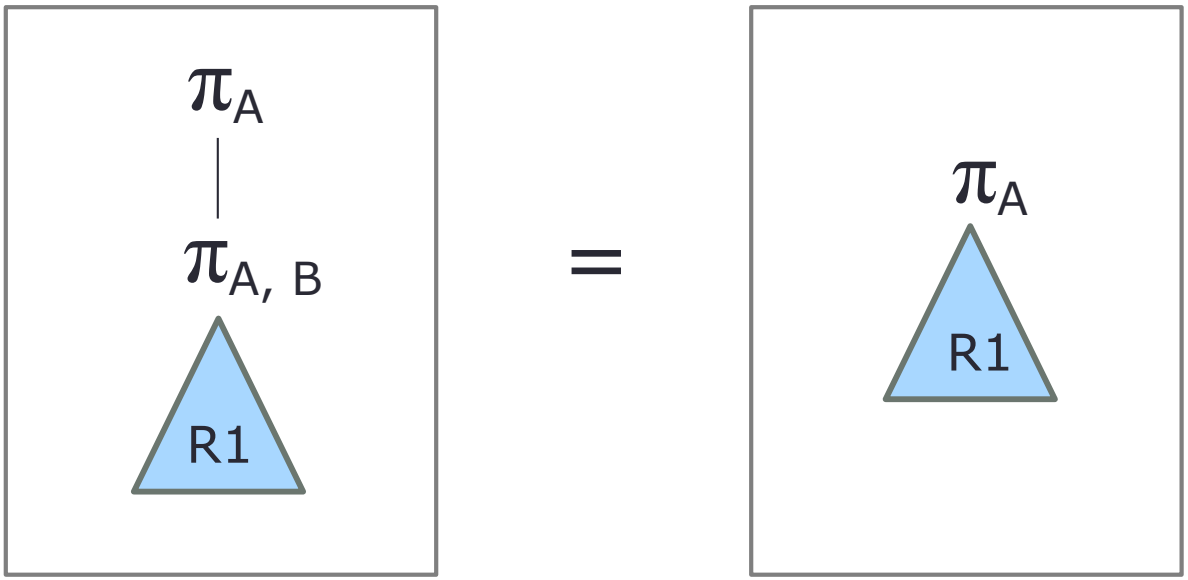
Execution

Plan Enumeration (RA to RA)

- Some queries can be expressed in different ways
- RA formulation of a query is important in query processing and optimization
  - RA specifies the order of operations
  - The order can largely determine how efficient the query plan will be
- Why RA equivalences?
  - Simplify queries
  - Make queries faster

Explore equivalent RA plans

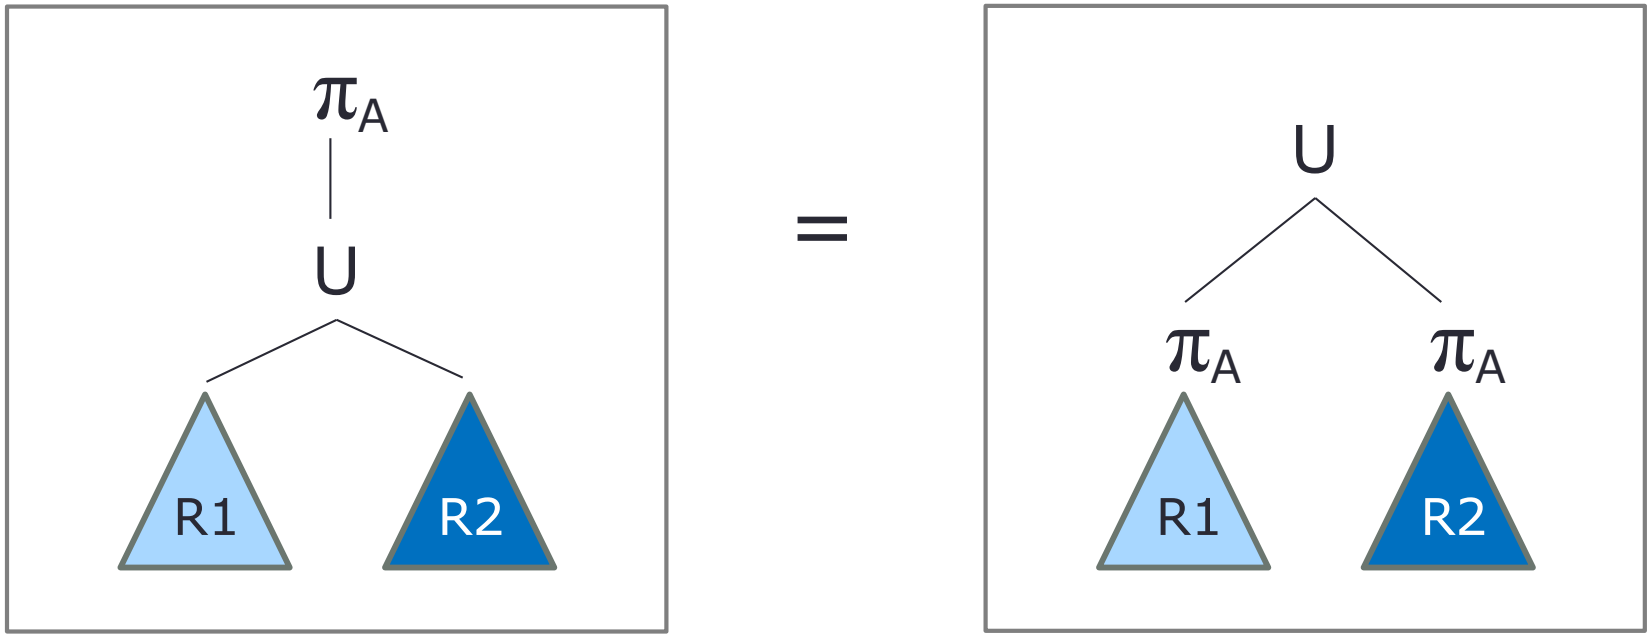
Simplify "Project"



Successive projects can reduced to the final project
only the last project has to be executed

A and *B* are sets of attributes; *R1* is a relation

"Project" and "Union"



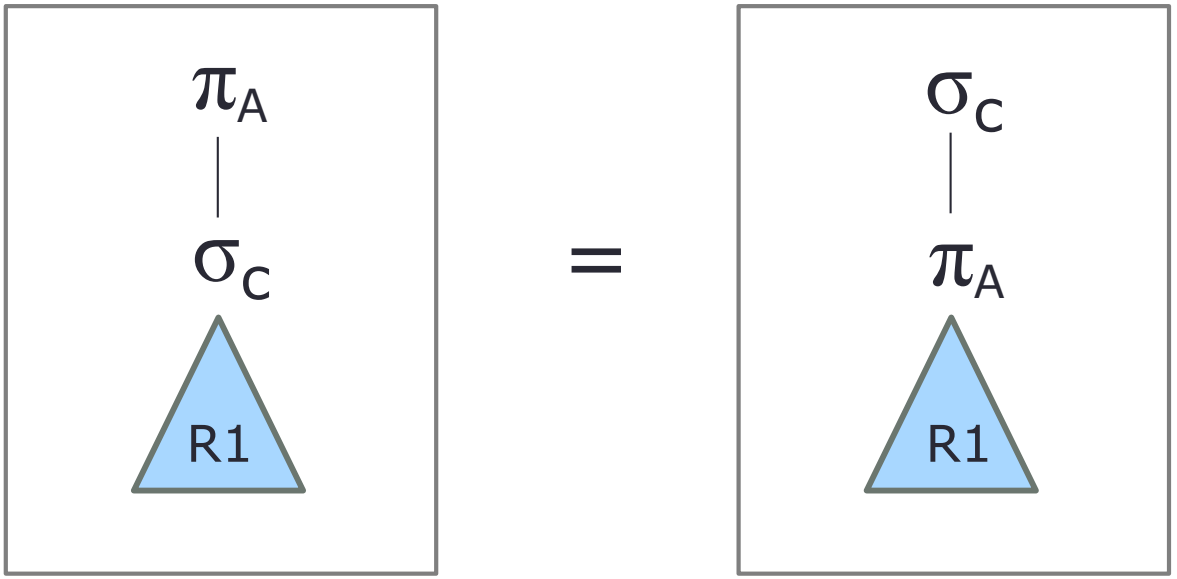
Make sure the schema matches

Note: this may not work with intersection or set difference

Project distributes over union

A is a set of attributes; *R1* and *R2* are relations

"Select" and "Project"

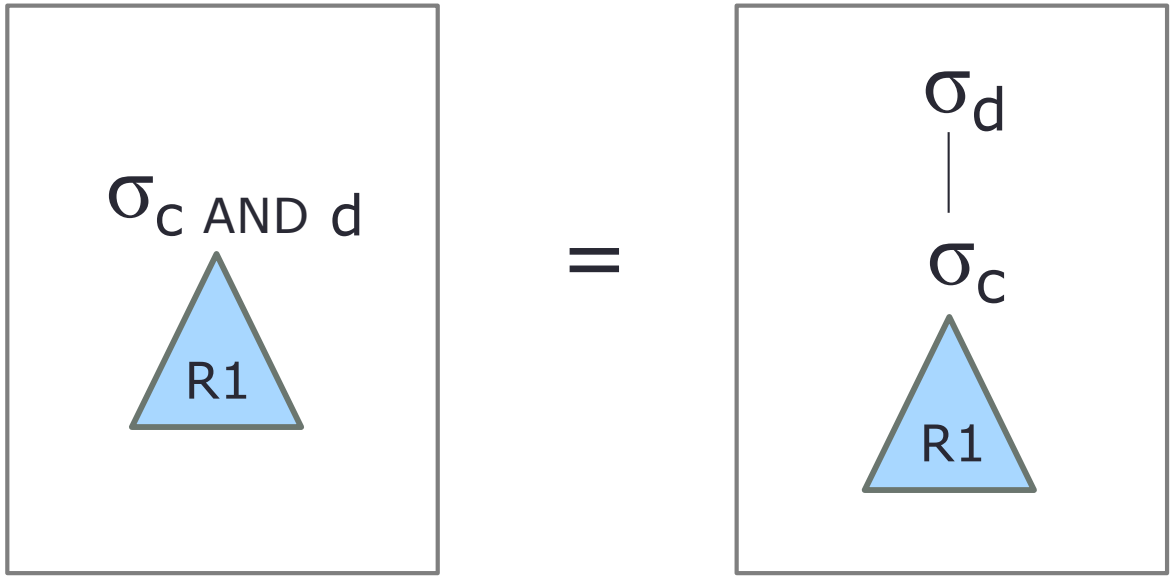


If *C* only references attributes in *A*

Select and project sometimes commute if the condition involves only the attributes in the project list

A is a set of attributes; *C* is a set of Boolean conditions; *R1* is a relation

"Select" and "AND"

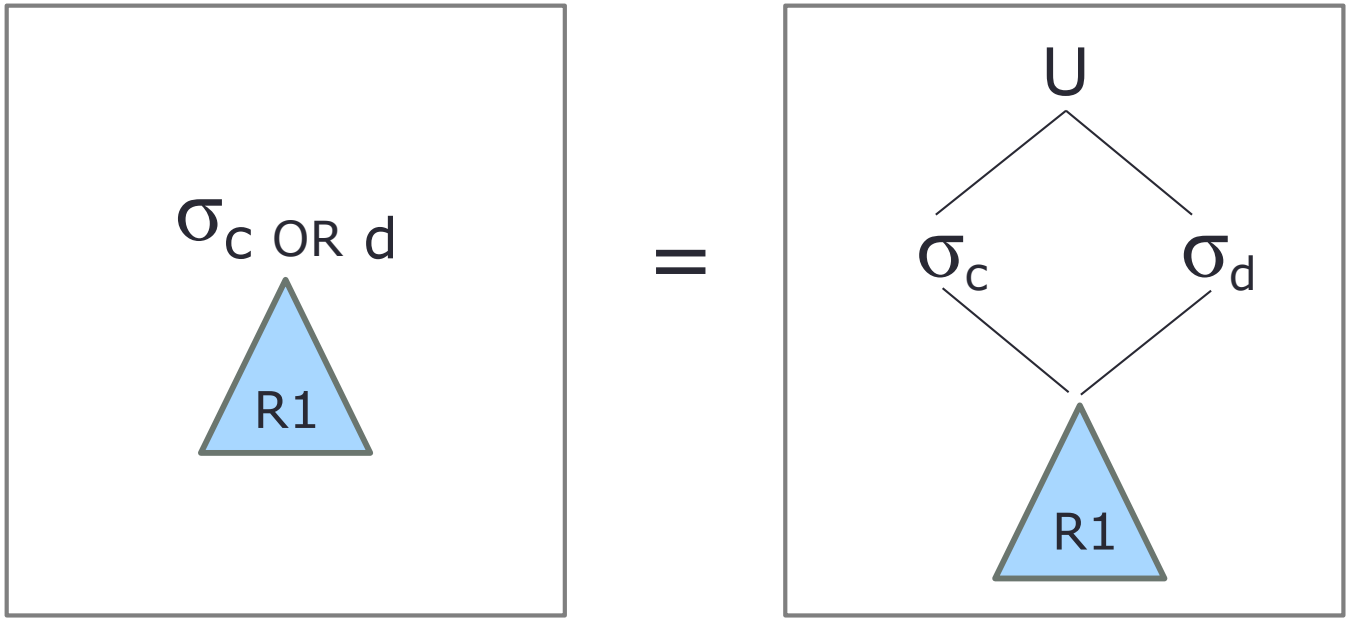


Conjunctive selects can cascade into individual selects

$$\sigma_{c \text{ AND } d}(R1)) = \sigma_d(\sigma_c(R1))$$

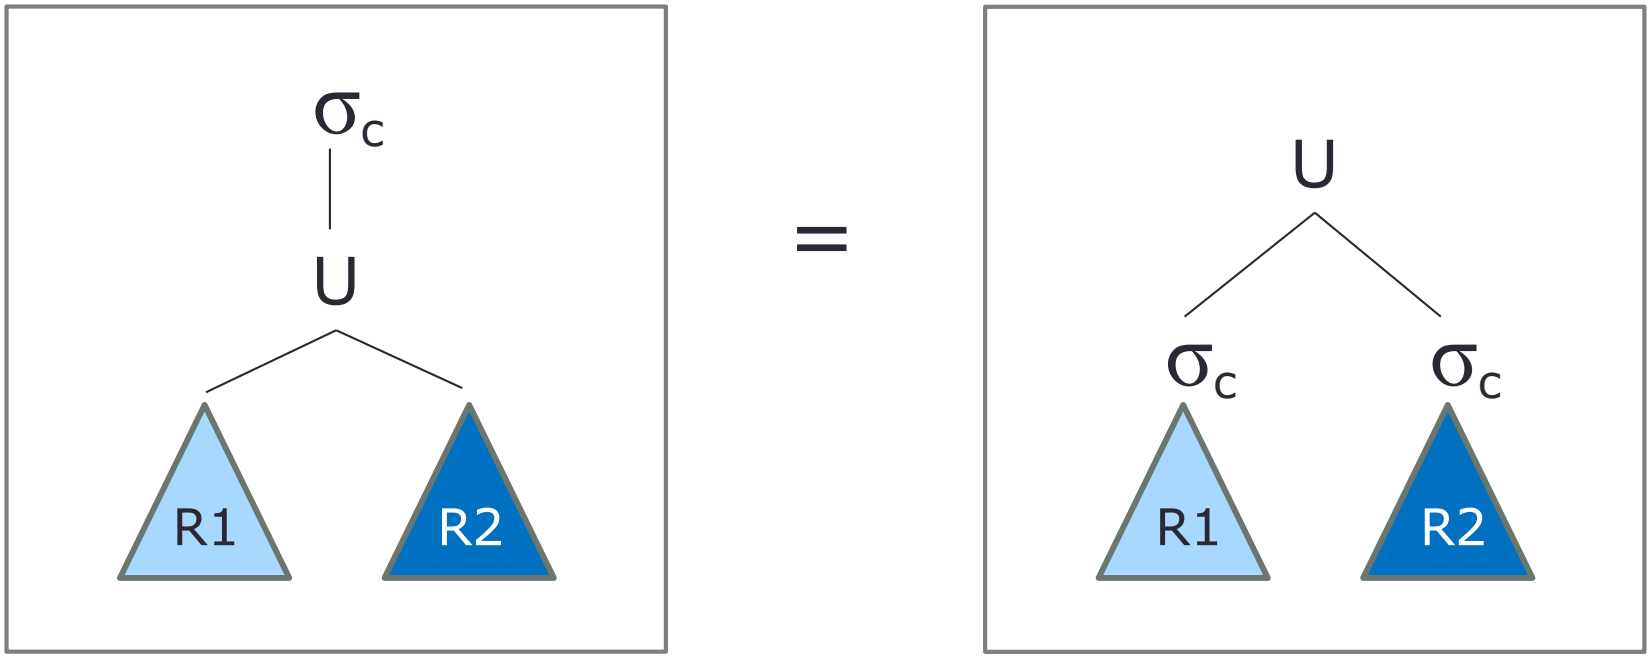
c and *d* are Boolean conditions; *R1* is a relation

"Select" and "OR"



c and *d* are Boolean conditions; *R1* is a relation

"Select" and "Union"

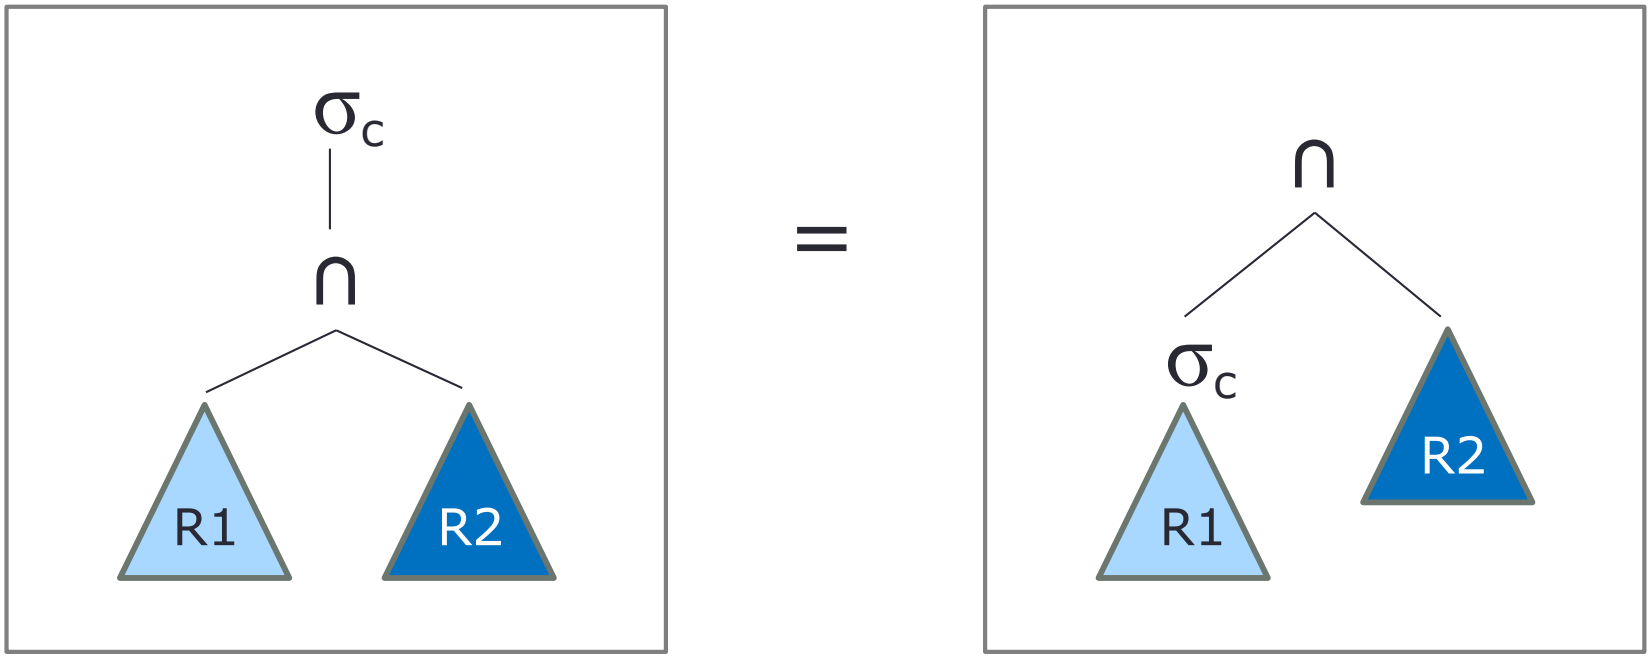


If *C* references attributes in *R1* and *R2*

Perform "Select" operation as early as possible

C is a set of Boolean conditions; *R1* and *R2* are relations

"Select" and "Intersect"

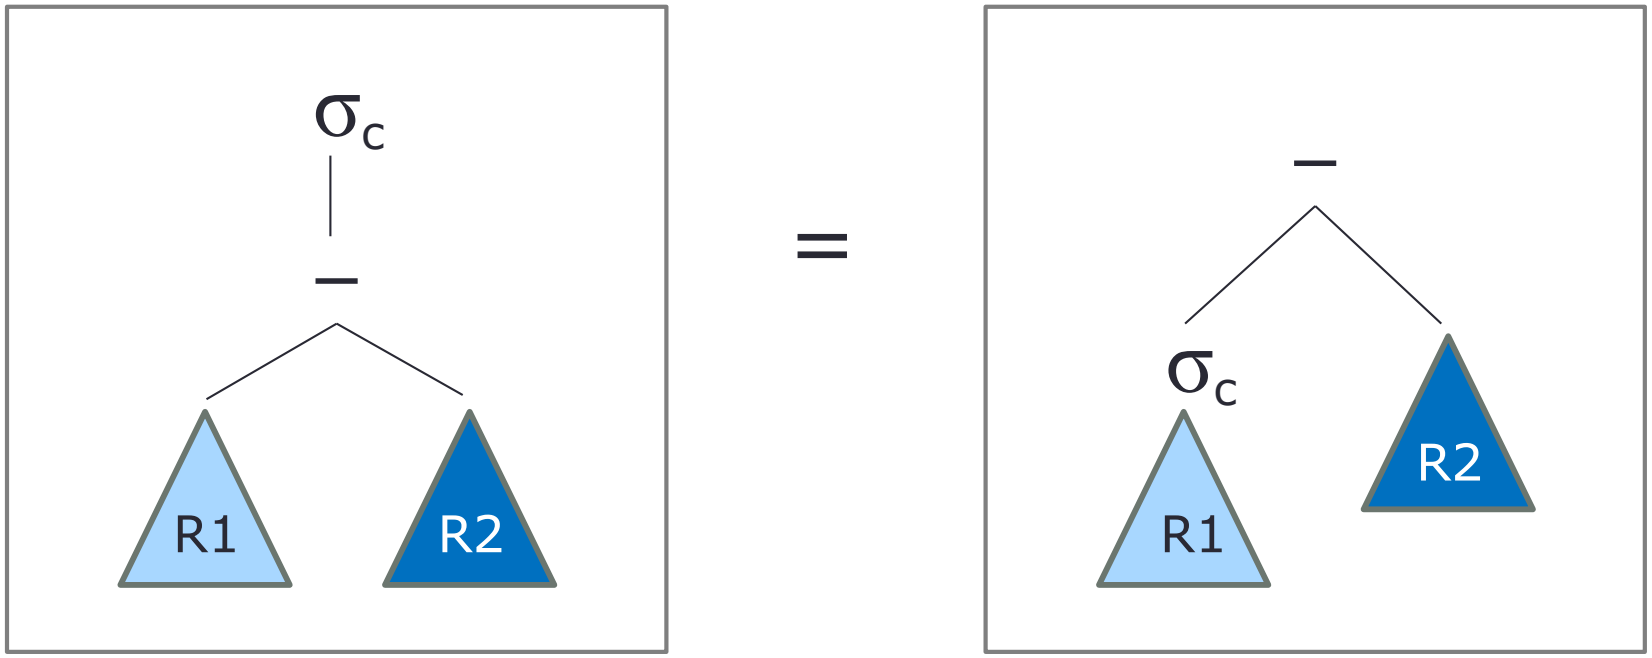


If *C* only references attributes in *R1*

Perform "Select" operation as early as possible

C is a set of Boolean conditions; *R1* and *R2* are relations

"Select" and "Difference"



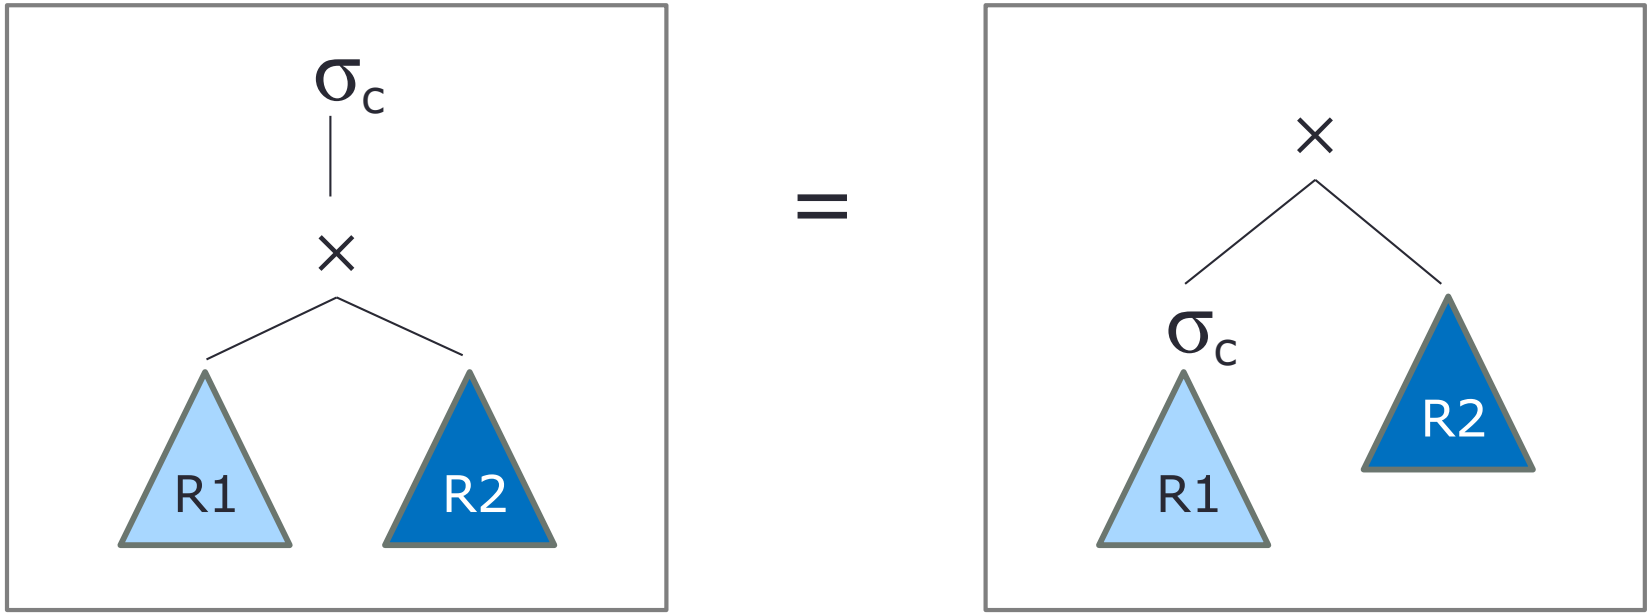
If *C* only references attributes in *R1*

Perform "Select" operation as early as possible

"EXCEPT" in SQL is equivalent to set "difference" in RA

C is a set of Boolean conditions; *R1* and *R2* are relations

"Select" and "Cartesian Product"



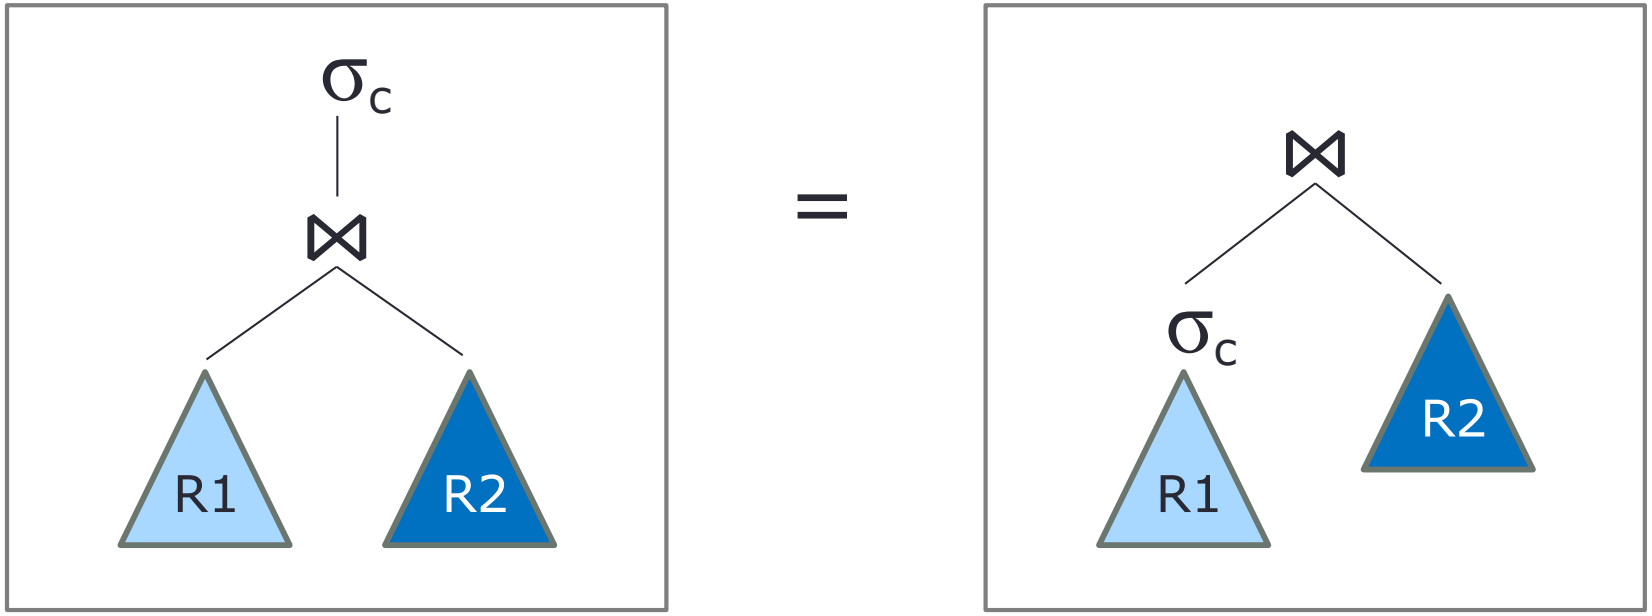
If *C* only references attributes in *R1*

Select and product sometimes commute

Perform "Select" operation as early as possible

C is a set of Boolean conditions; *R1* and *R2* are relations

"Select" and "Join"



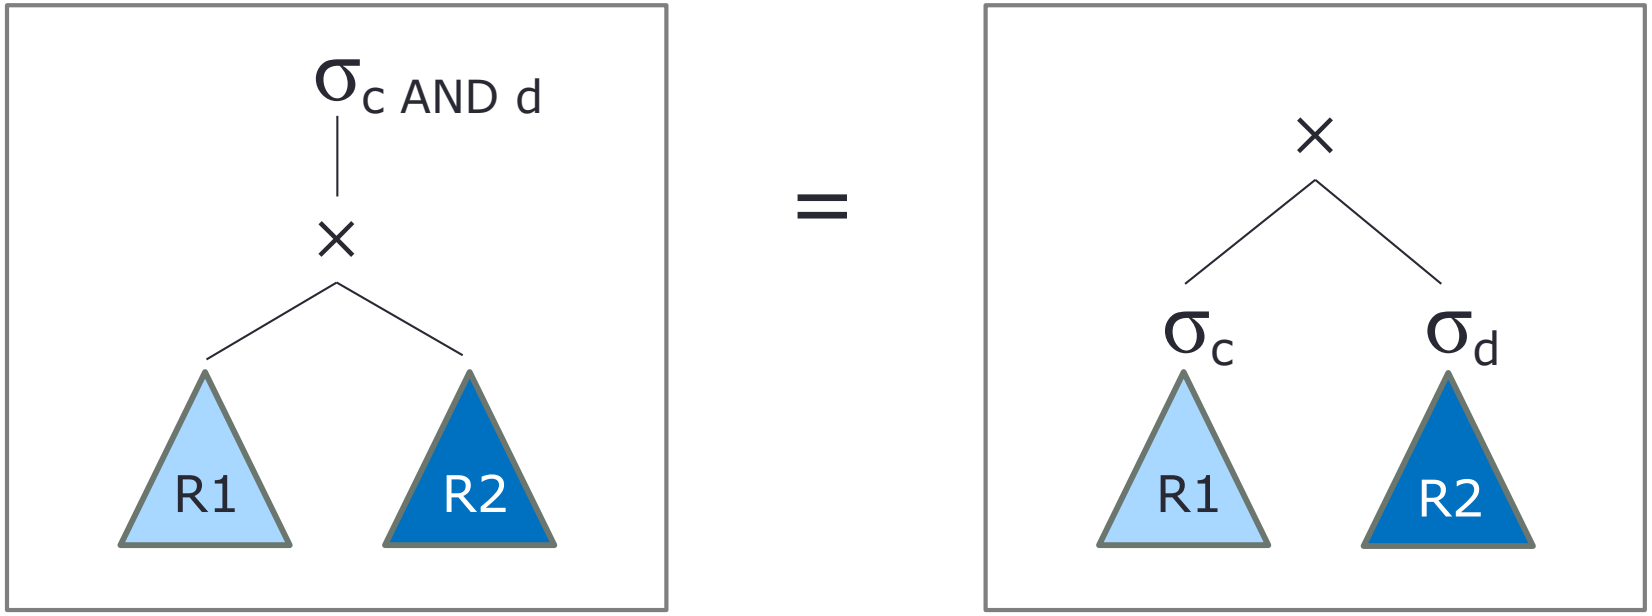
If *C* only references attributes in *R1*

Select and join sometimes commute

Perform "Select" operation as early as possible

C is a set of Boolean conditions; *R1* and *R2* are relations

"Select" and "Cartesian Product"



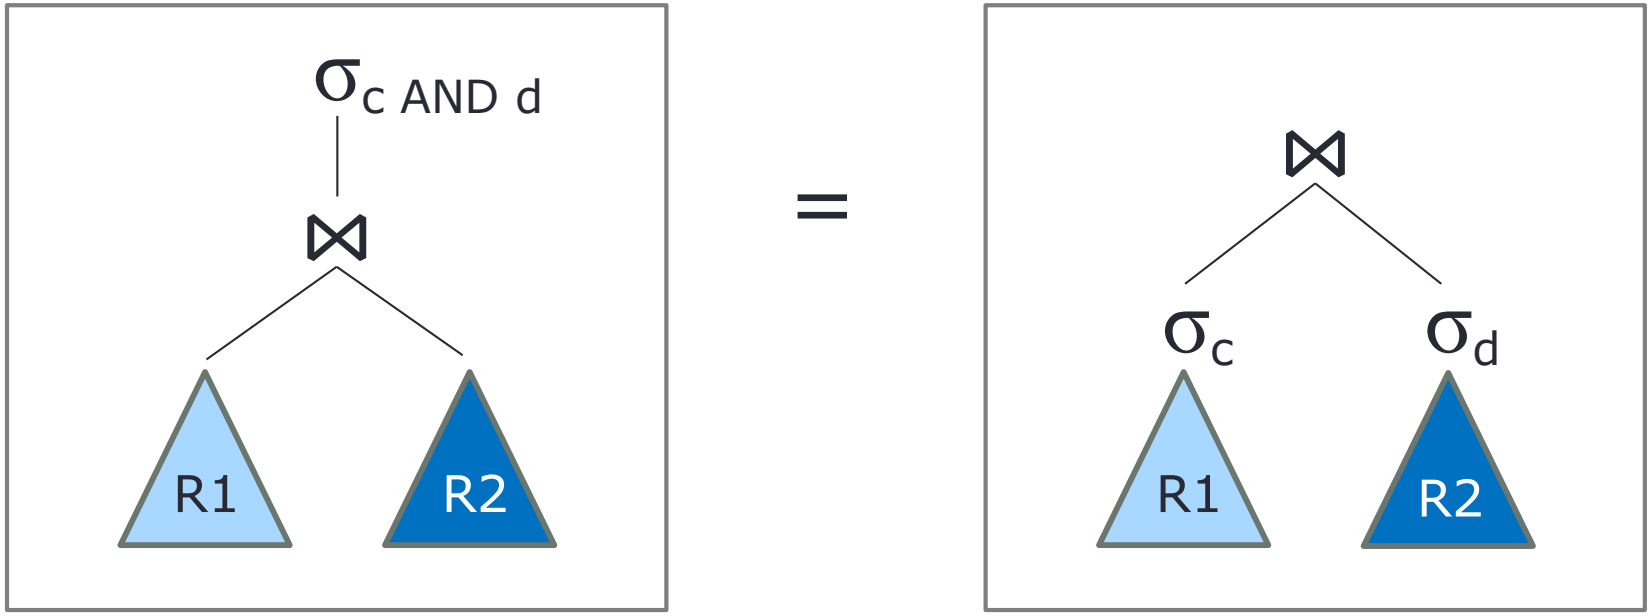
If *c* references attributes in *R1* and *d* references attributes in *R2*

Select sometimes distribute over product

Perform "Select" operation as early as possible

C is a set of Boolean conditions; *R1* and *R2* are relations

"Select" and "Join"



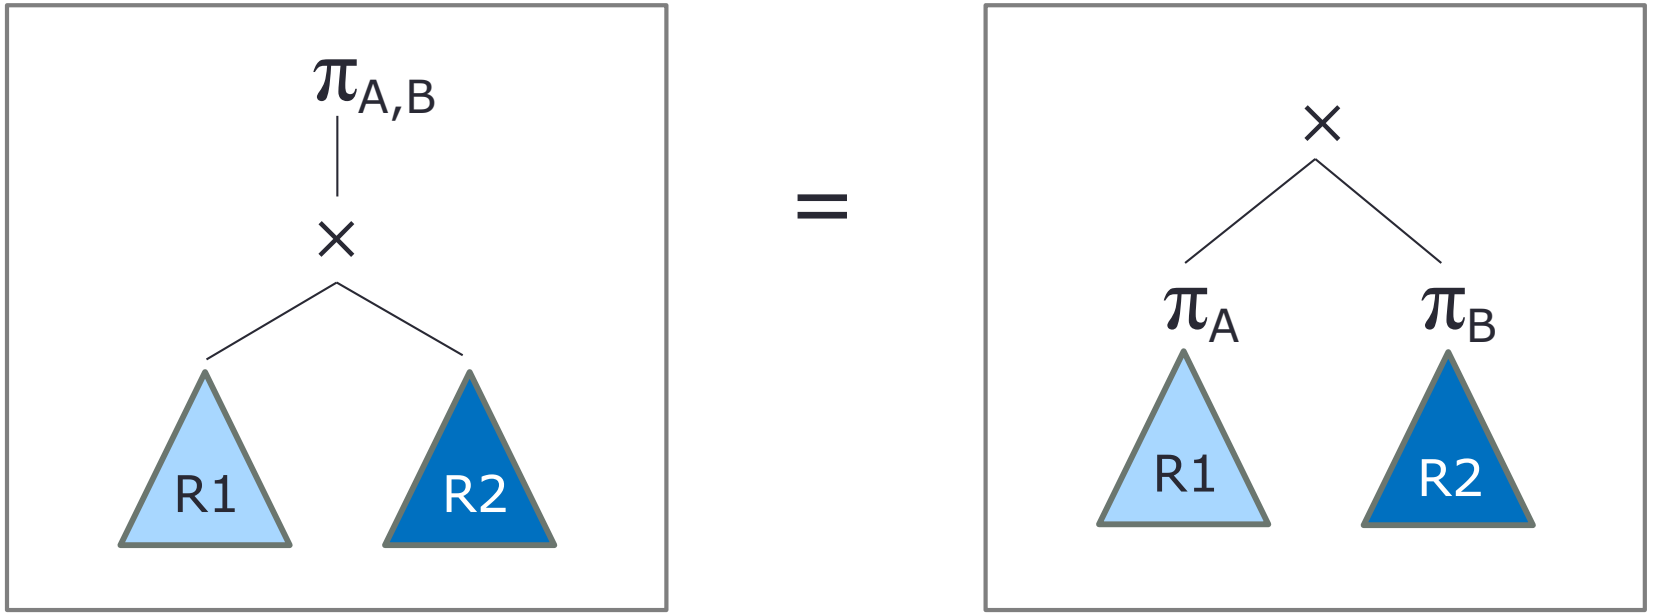
If *c* references attributes in *R1* and *d* references attributes in *R2*

Select sometimes distribute over join

Perform "Select" operation as early as possible

C is a set of Boolean conditions; *R1* and *R2* are relations

"Project" and "Cartesian Product"

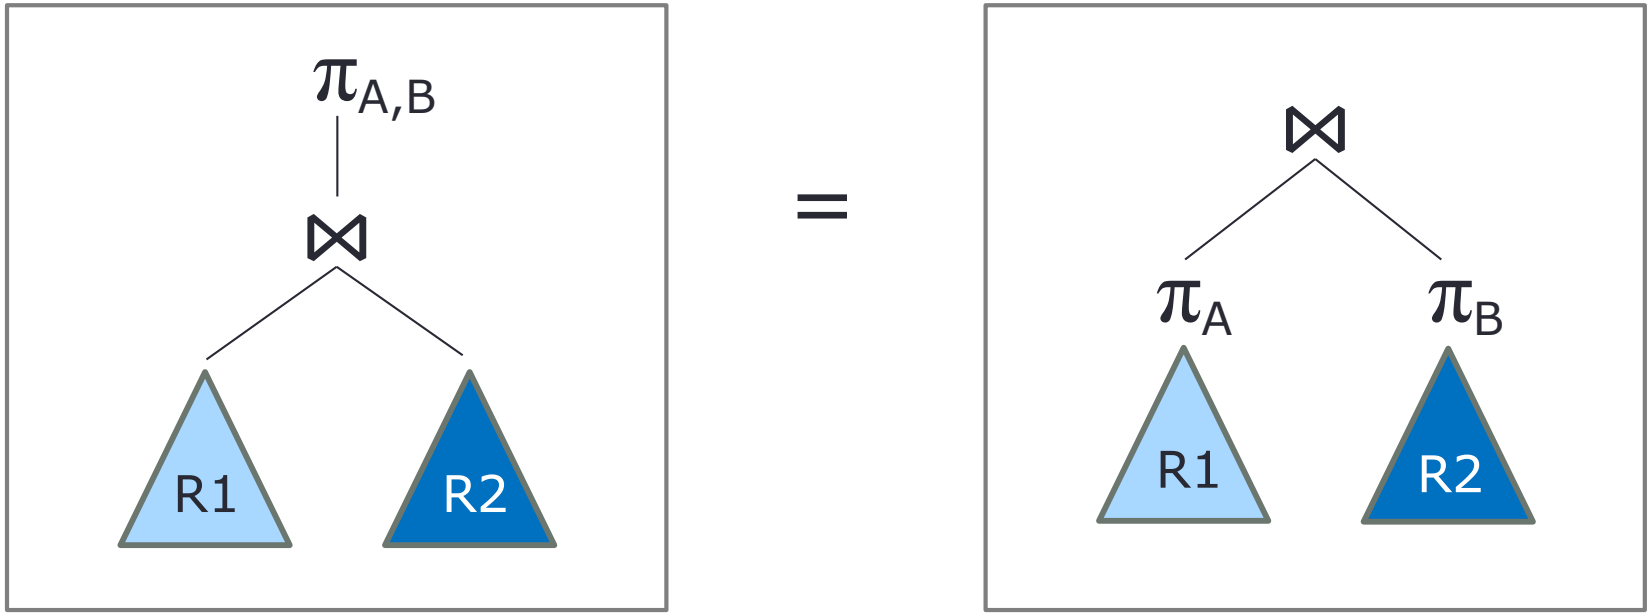


If *A* contains attributes in *R1* and *B* contains attributes in *R2*

Project sometimes distribute over product

A and *B* are sets of attributes; *R1* and *R2* are relations

"Project" and "Join"

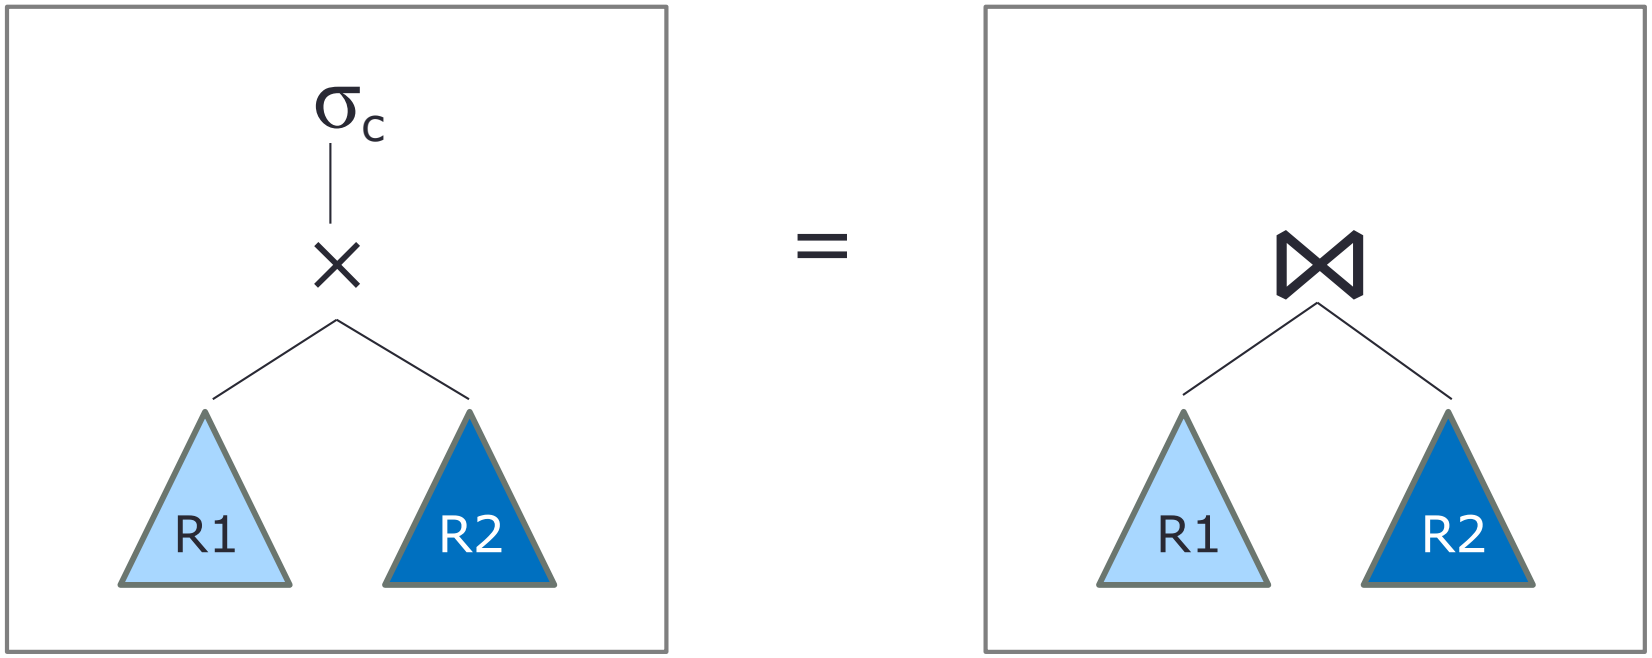


If *A* contains attributes in *R1* and *B* contains attributes in *R2*

Project sometimes distribute over join

A and *B* are sets of attributes; *R1* and *R2* are relations

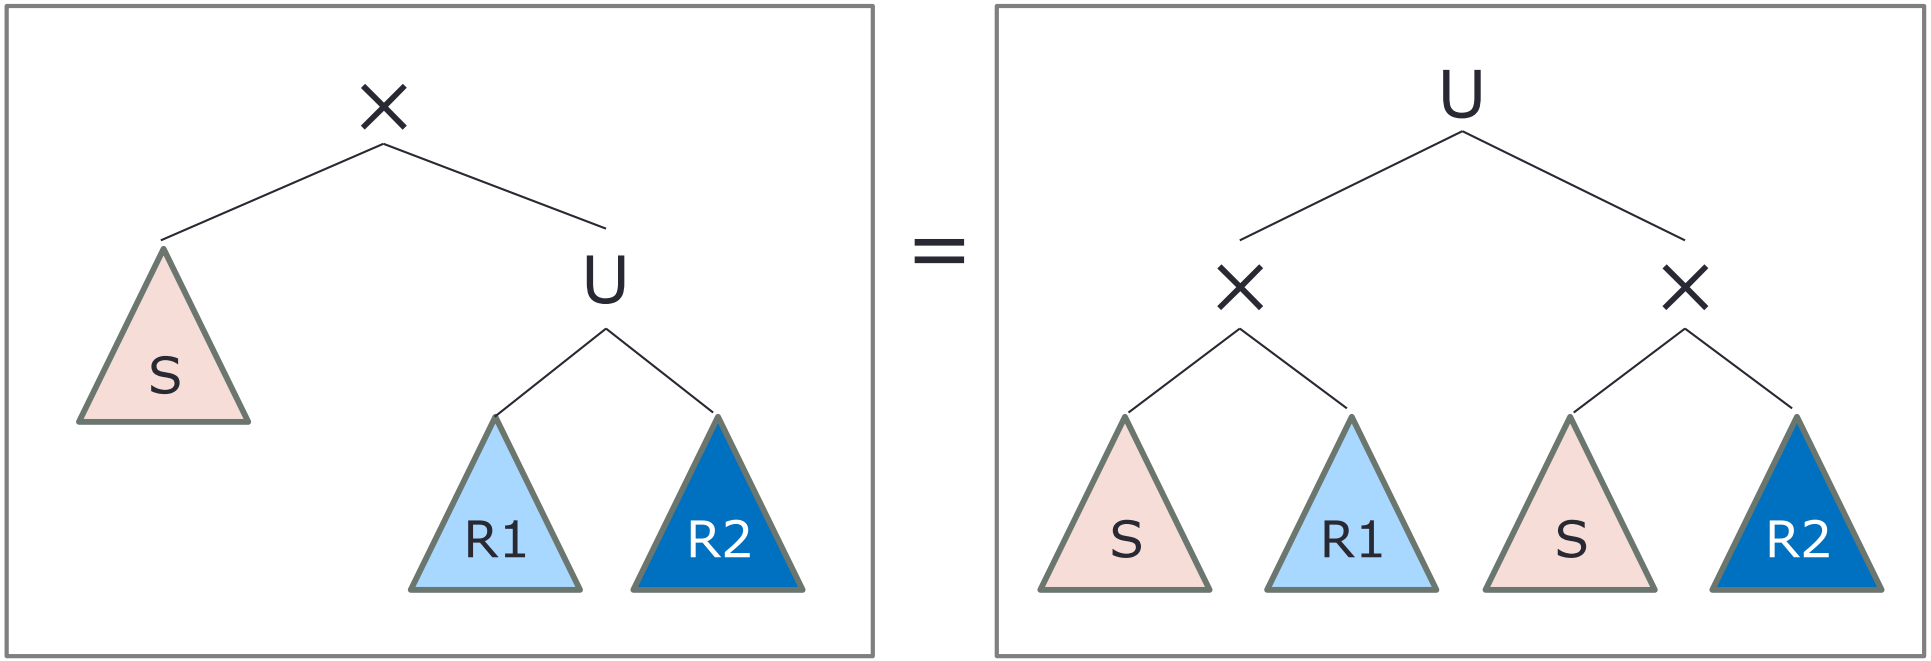
"Cartesian Product" and "Join"



Assume *C* contains attributes that are used to combine relations

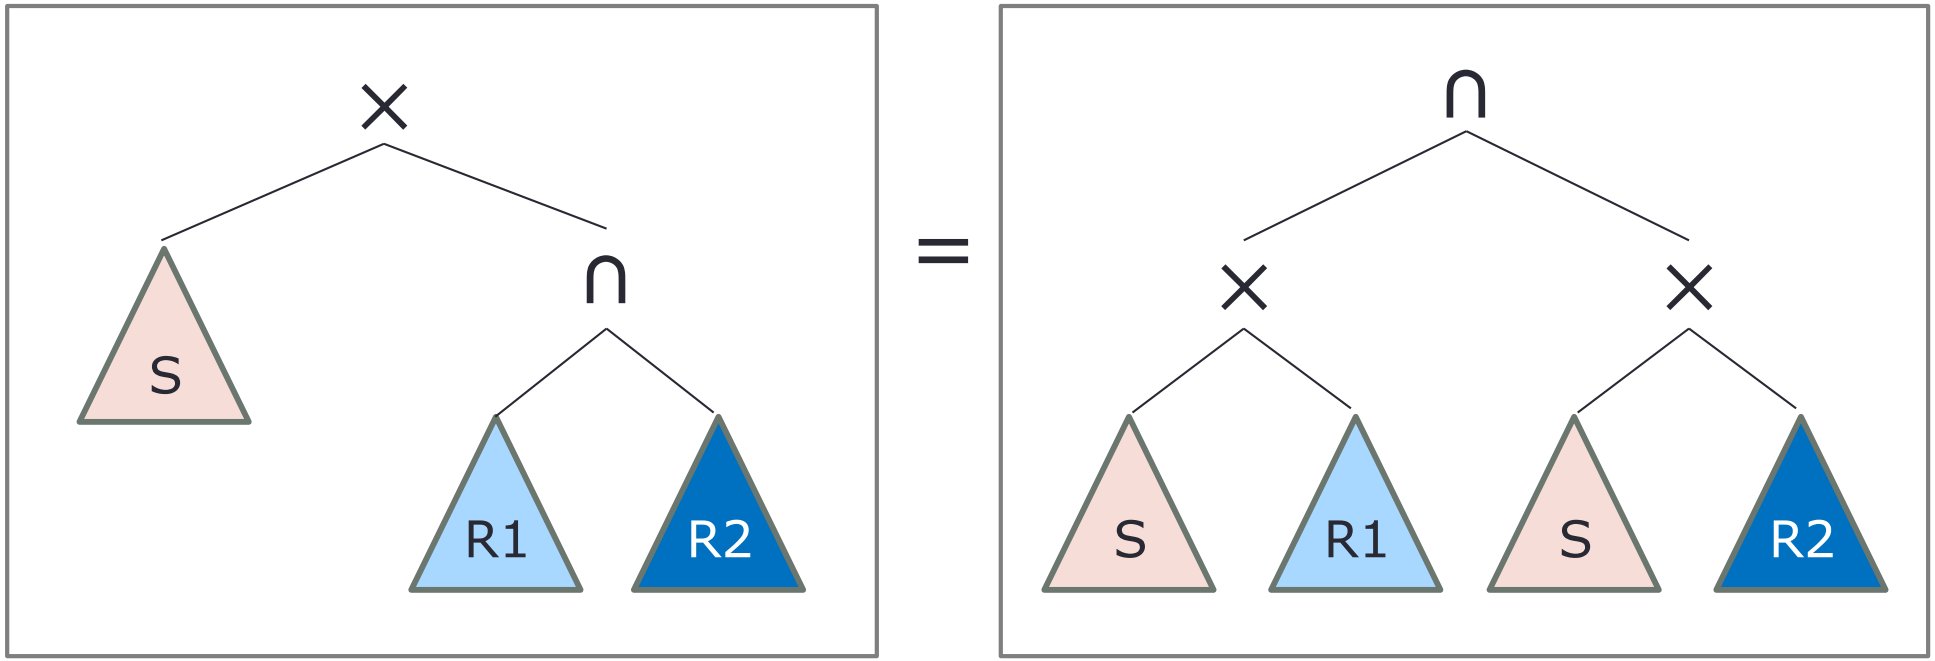
C is a set of Boolean conditions; *R1* and *R2* are relations

"Cartesian Product" and "Union"



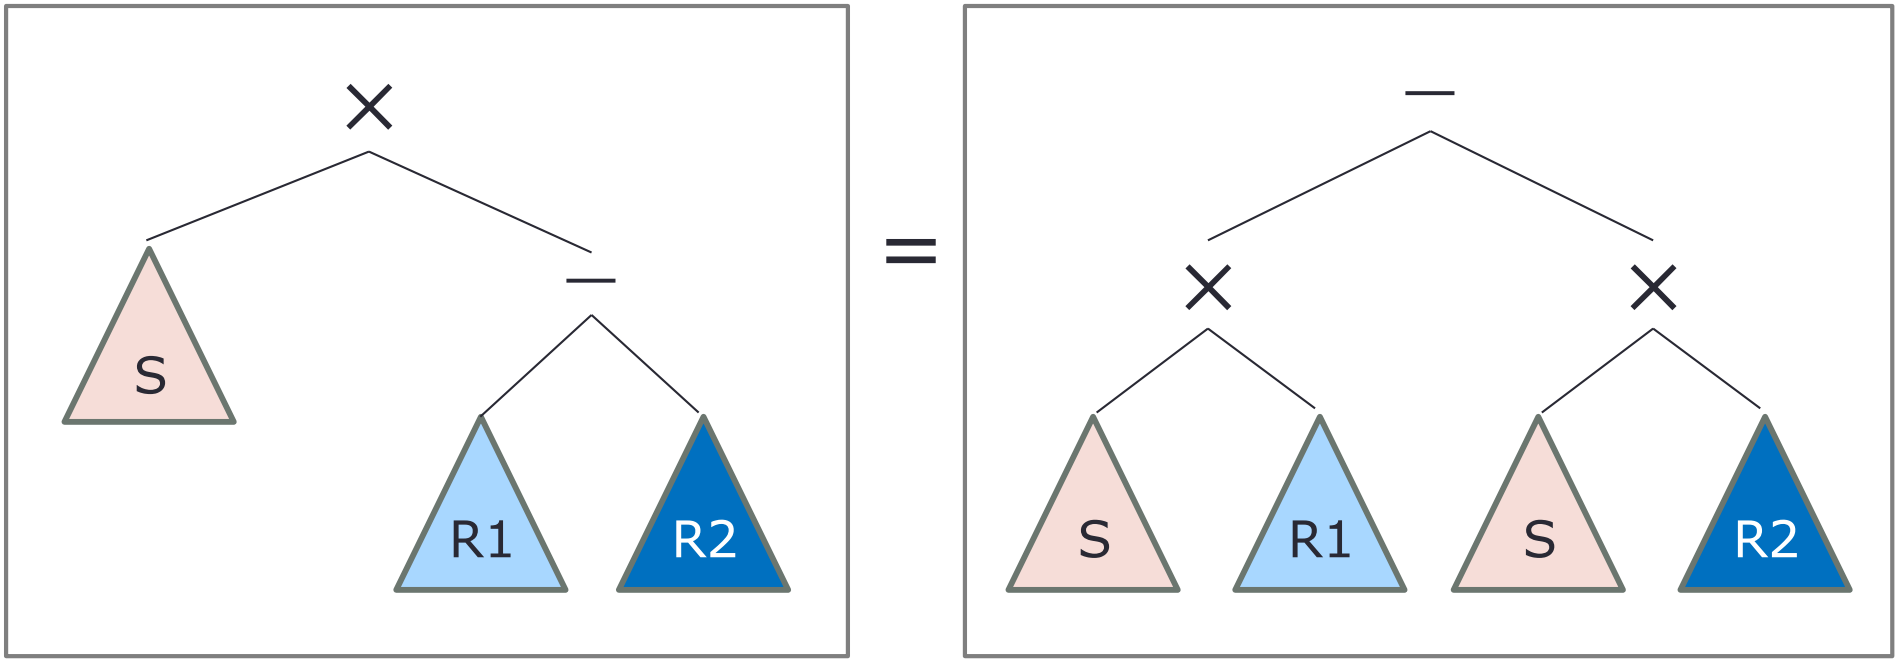
R1, *R2,* and *S* are relations

"Cartesian Product" and " Intersect"



R1, *R2,* and *S* are relations

"Cartesian Product" and "Difference"



"EXCEPT" in SQL is equivalent to set difference in RA

R1, *R2,* and *S* are relations

Let's Try: Equivalent RA (1)

Consider the Sailors database

```
Boats (bid, bname, color)
Sailors (sid, sname, rating, age)
Reserves (sid, bid, day)
```

Find the names of sailors who have reserved a red or green boat

$$\pi_{\text{sname}}(\sigma_{\text{color='red' OR color='green'}} (\text{Sailors} \bowtie \text{Reserves} \bowtie \text{Boats}))$$

Can you think of an equivalent RA?

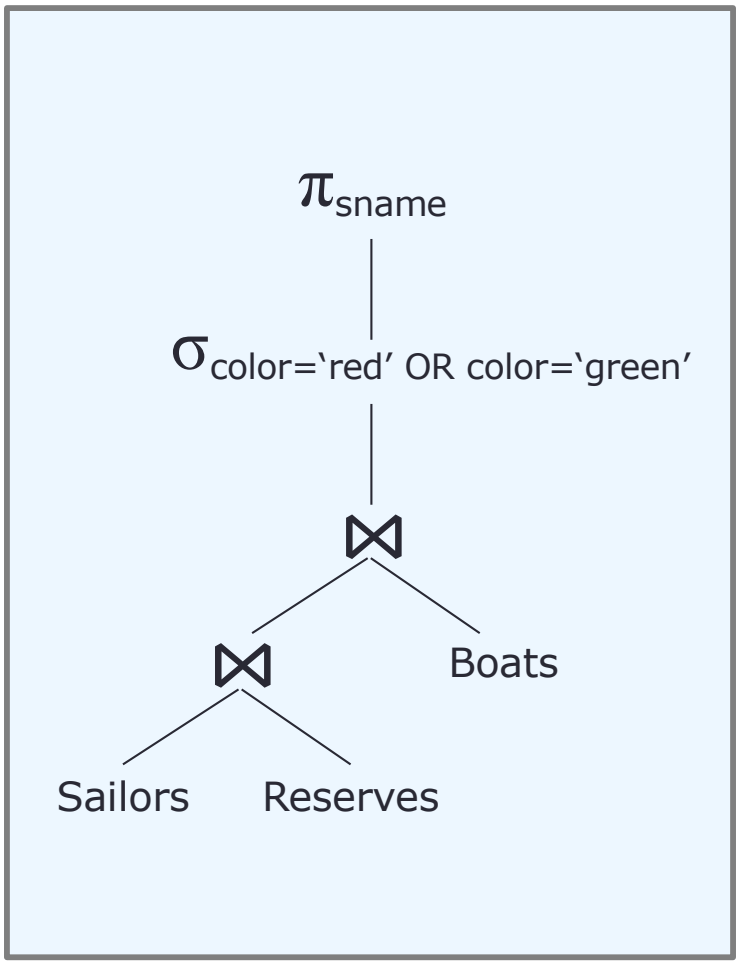
$$\pi_{\text{sname}}(\sigma_{\text{color='red'}}(\text{Sailors} \bowtie \text{Reserves} \bowtie \text{Boats})) \cup$$

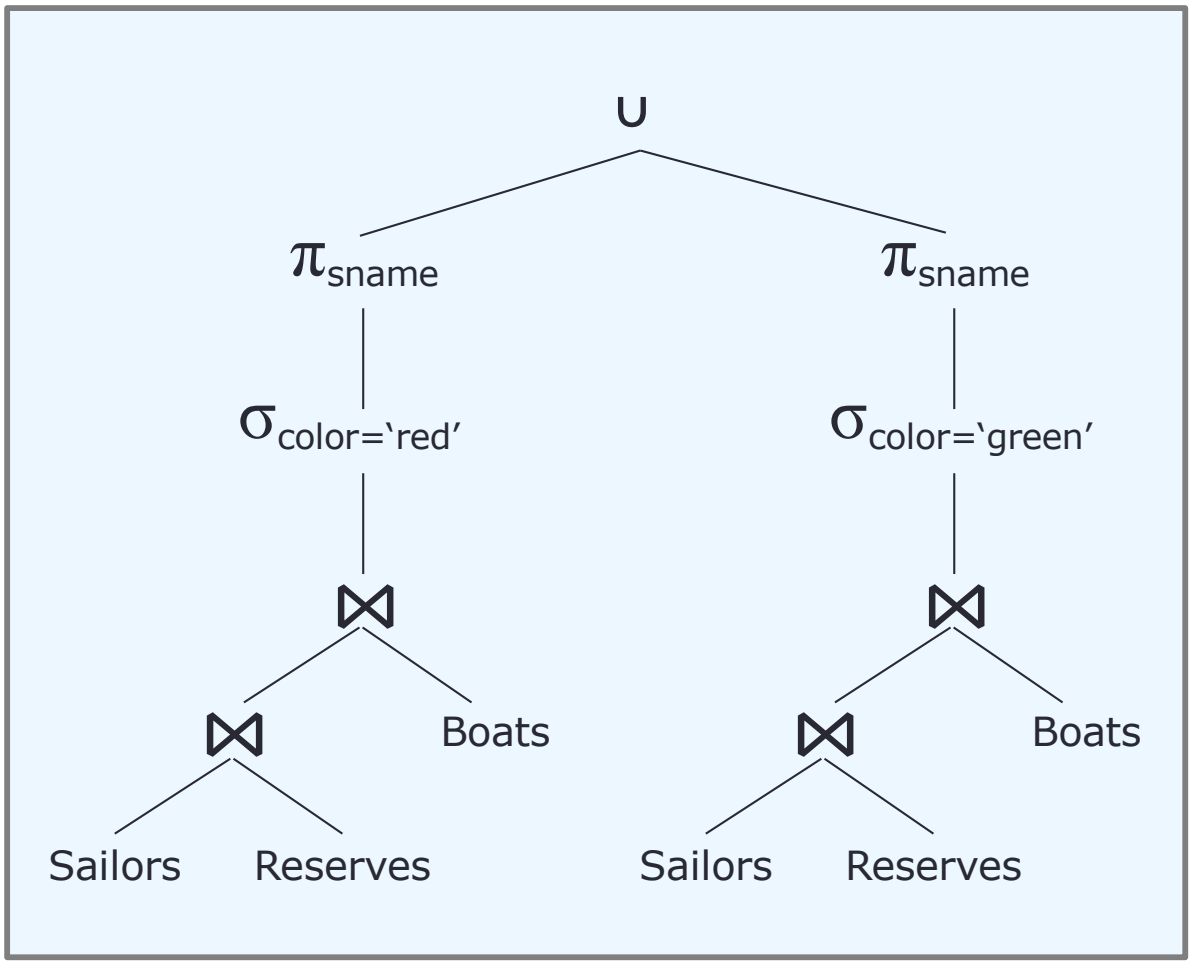
$$\pi_{\text{sname}}(\sigma_{\text{color='green'}}(\text{Sailors} \bowtie \text{Reserves} \bowtie \text{Boats}))$$

Let's Try: Equivalent RA (1)

$\pi_{sname}(\sigma_{color='red' \text{ OR } color='green'}$ (
Sailors $\bowtie$ Reserves $\bowtie$ Boats))

$\pi_{sname}(\sigma_{color='red'}$(Sailors $\bowtie$ Reserves $\bowtie$ Boats)) $\cup$
$\pi_{sname}(\sigma_{color='green'}$(Sailors $\bowtie$ Reserves $\bowtie$ Boats))





Let's Try: Equivalent RA (2)

Consider the Sailors database

```
Boats (bid, bname, color)
Sailors (sid, sname, rating, age)
Reserves (sid, bid, day)
```

Find the names of sailors who have reserved boat 103

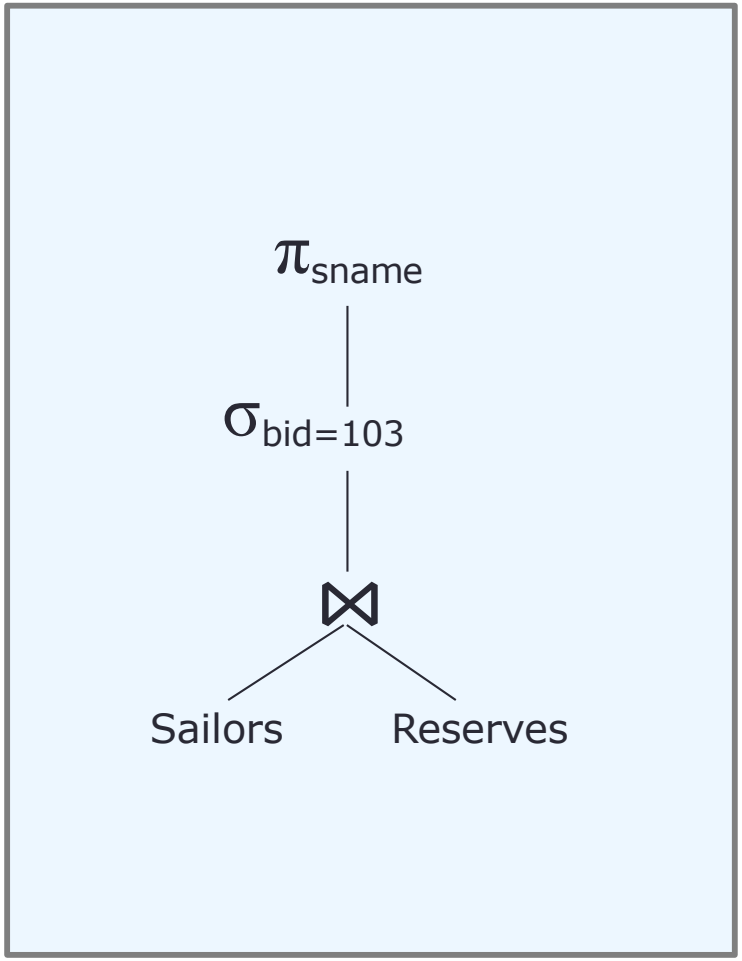
$$\pi_{sname}(\sigma_{bid=103}(Sailors \bowtie Reserves))$$

Can you think of an equivalent RA?

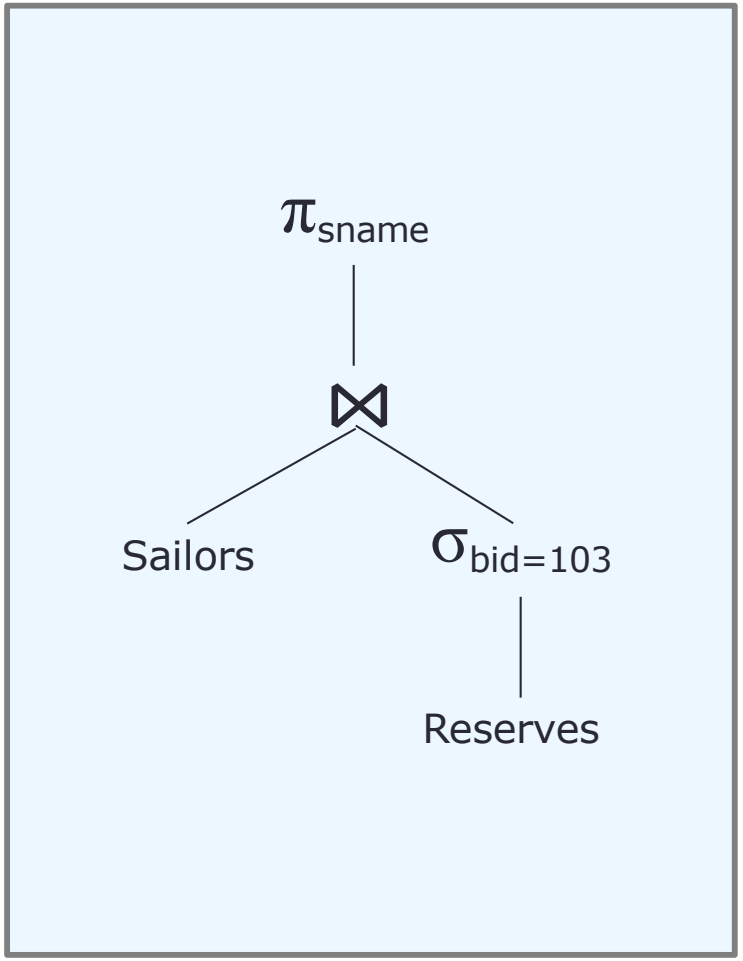
$$\pi_{sname}(Sailors \bowtie \sigma_{bid=103}(Reserves))$$

Let's Try: Equivalent RA (2)

$\pi_{sname}(\sigma_{bid=103}(Sailors \bowtie Reserves))$



$\pi_{sname}(Sailors \bowtie \sigma_{bid=103}(Reserves))$



Let's Try: Equivalent RA (3)

Consider the Sailors database

```
Boats (bid, bname, color)
Sailors (sid, sname, rating, age)
Reserves (sid, bid, day)
```

Find the IDs and names of sailors who have not reserved a boat

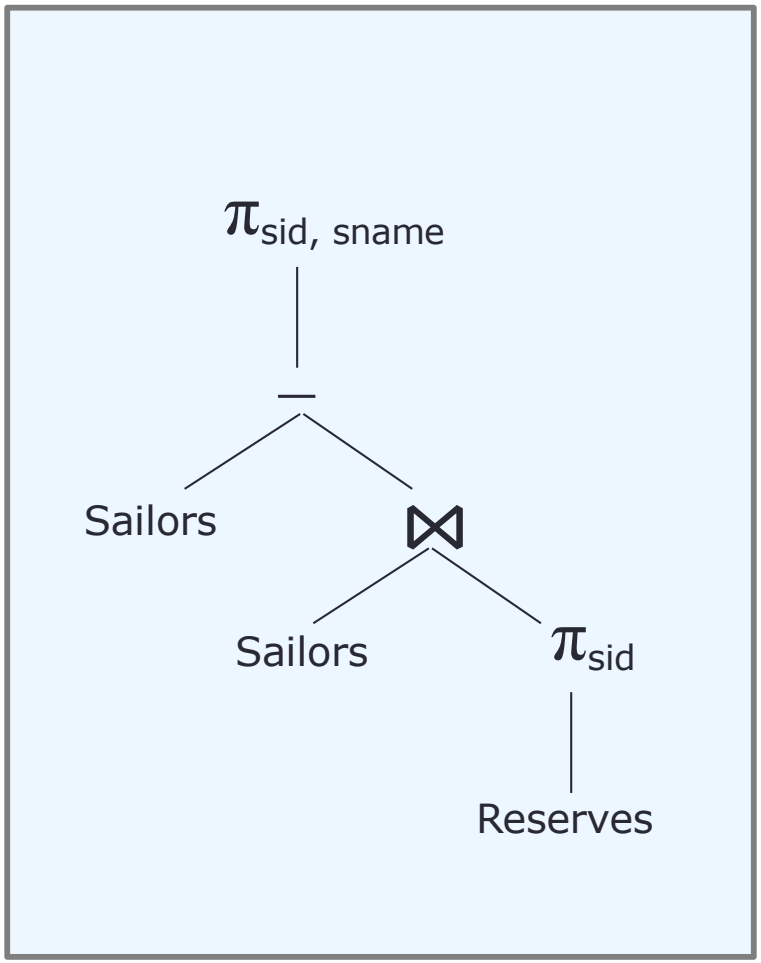
$$\pi_{\text{sid, sname}}(\text{Sailors} - (\text{Sailors} \bowtie \pi_{\text{sid}}(\text{Reserves})))$$

Can you think of an equivalent RA?

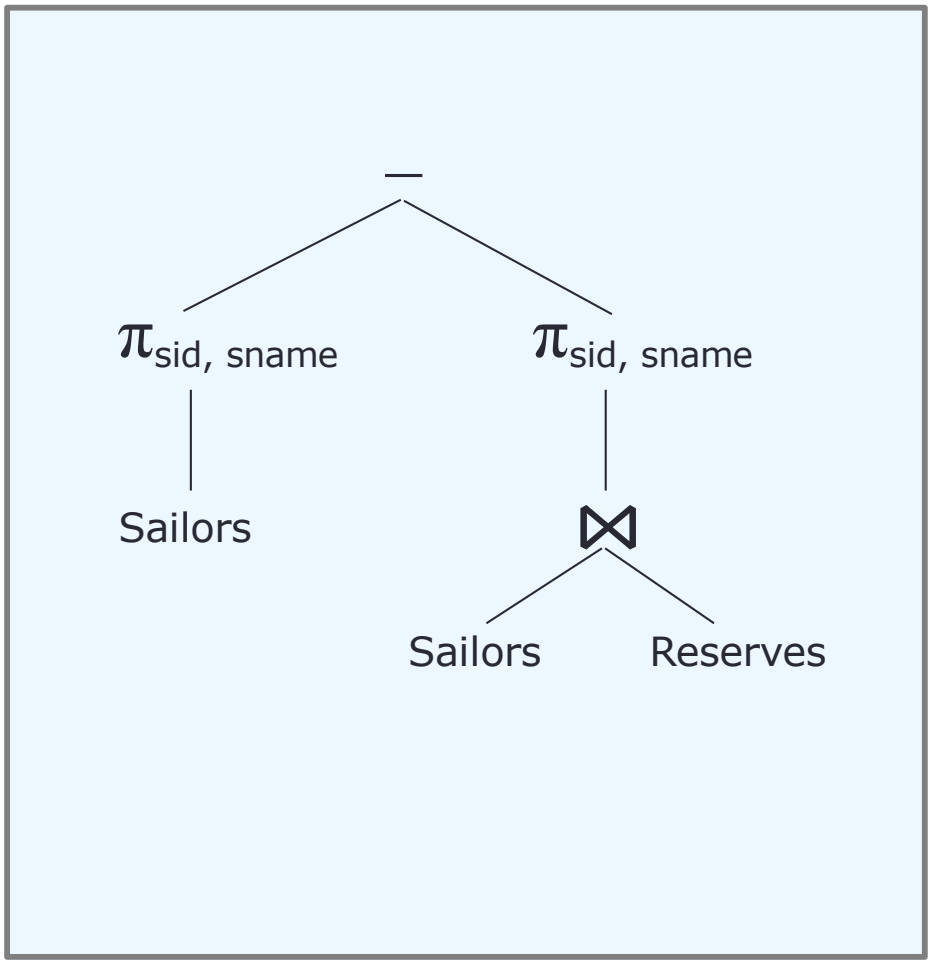
$$\pi_{\text{sid, sname}}(\text{Sailors}) - \pi_{\text{sid, sname}}(\text{Sailors} \bowtie \text{Reserves})$$

Let's Try: Equivalent RA (3)

$\pi_{sid, sname}(Sailors - (Sailors \bowtie \pi_{sid}(Reserves))$



$\pi_{sid, sname}(Sailors) -$
$\pi_{sid, sname}(Sailors \bowtie Reserves)$



More RA Equivalences

- All joins and Cartesian products are commutative

  $R \times S = S \times R$ (mostly)

  $R \bowtie S = S \bowtie R$

- Joins and Cartesian products are associative

  $(R \times S) \times T = R \times (S \times T)$

  $(R \bowtie S) \bowtie T = R \bowtie (S \bowtie T)$

- Select is commutative

  $\sigma_c(\sigma_d(R)) = \sigma_d(\sigma_c(R))$

- Union and intersection are commutative

  $R \cup S = S \cup R$

  $R \cap S = S \cap R$

- Union and intersection are associative

  $(R \cup S) \cup T = R \cup (S \cup T)$

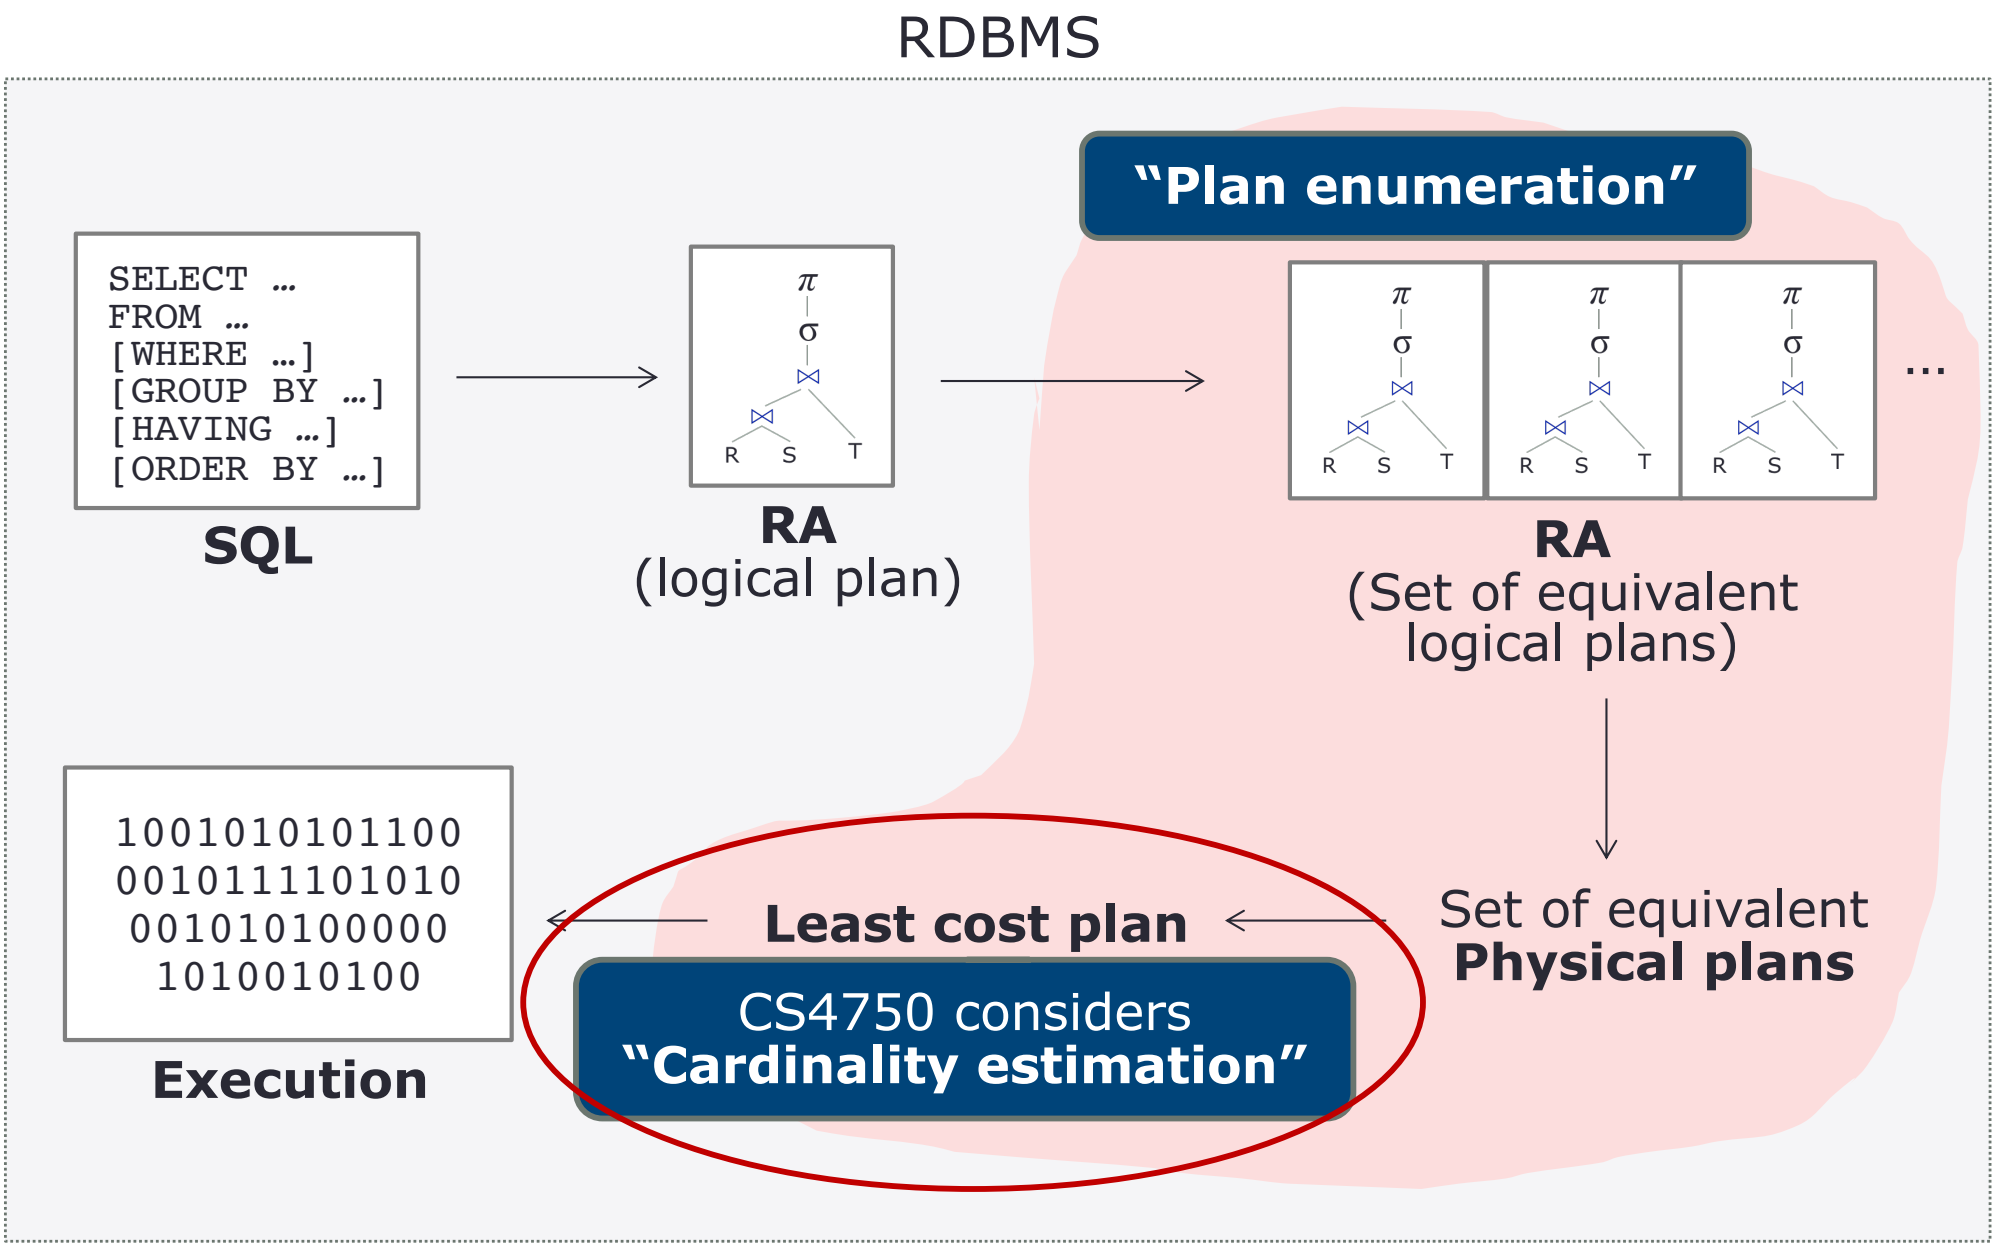
  $(R \cap S) \cap T = R \cap (S \cap T)$

Plenty more equivalences

How to remember?
Use the definitions

R, *S*, and *T* are relations

Overview: Query Optimization



Disclaimer

Cost estimation is an active research topic.

Equations and methods discussed here form a foundation of concepts, but usually cannot compare to a commercialized solution.

General Idea on Plan Selection

- Which equivalent RA leads to the most efficient algorithm?
- What algorithm should we use to implement each operation?
- How should the operations pass data from one to the other?

Depends on info available to the query optimizer

- Size of each relation
- Statistics (#blocks, #tuples, #distinct values for an attribute)
- Indexes
- Layout of data on disk

For this class, we assume

- Disk-based storage – HDD
- Row-based storage – tuples are stored contiguously
- HDD I/O cost (reading from disk) only considered
- Sequential disk reads
- A block can be read at once
- No data preloaded

Cardinality Estimation

Estimate the **number of tuples** in the output of each RA operator

Let's use the University database schema as a running example

```
Student (studId, lastName, fistName, major, credits)
Class (classNumber, facId, schedule, room)
Faculty (facId, name, department, rank)
Enroll (studId, classNumber, grade)
```

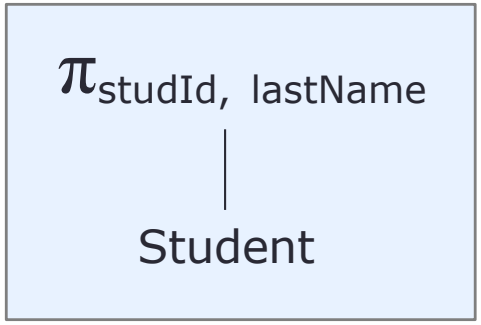
Estimation: SELECT

Assume we know the following information:

```
Student (studId, lastName, fistName, major, credits)

  T(Student) = 10,000          #of tuples
  V(lastName) = 9,500          #of distinct values
  V(major) = 10                #of distinct values
  Range(credits) = [1, 126)    range of values
```

```
SELECT studId, lastName
FROM Student
```



How many tuples do we expect this query to output?

10,000

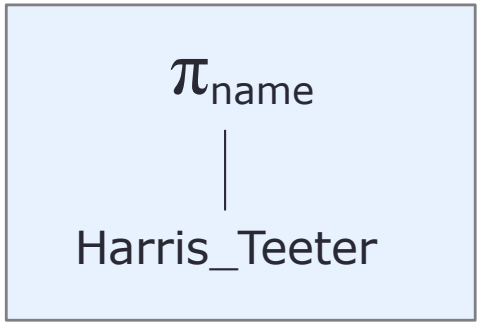
Let's Try: SELECT

Let's go grocery shopping. Assume we know the following info:

```
Harris_Teeter(id, name, category, price)

  T(Harris_Teeter) = 1,000        #of tuples
  V(name)          = 900          #of distinct values
  V(category)      = 10           #of distinct values
  V(price)         = 200          #of distinct values
  Range(price)     = [1,50)       range of values
```

```
SELECT name
FROM   Harris_Teeter
```



How many tuples do we expect this query to output?

SQL (1000) vs. RA (900)

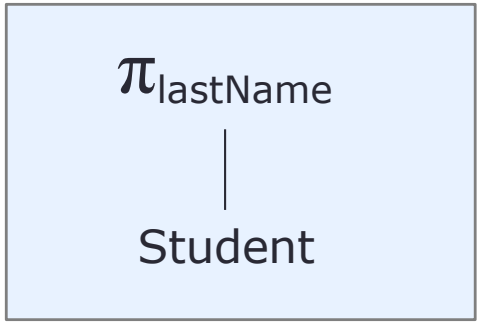
Estimation: DISTINCT

Assume we know the following information:

```
Student (studId, lastName, fistName, major, credits)

  T(Student) = 10,000          #of tuples
  V(lastName) = 9,500          #of distinct values
  V(major) = 10                #of distinct values
  Range(credits) = [1, 126)    range of values
```

```
SELECT DISTINCT lastName
FROM Student
```



How many tuples do we expect this query to output?

9,500

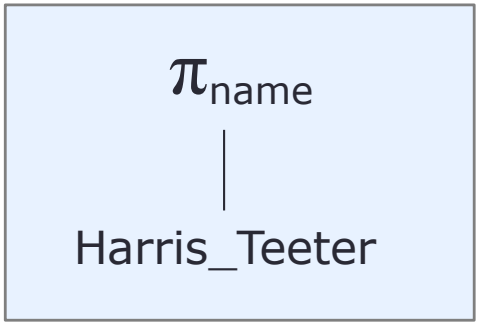
Let's Try: DISTINCT

Let's go grocery shopping. Assume we know the following info:

```
Harris_Teeter(id, name, category, price)

  T(Harris_Teeter) = 1,000        #of tuples
  V(name)          = 900          #of distinct values
  V(category)      = 10           #of distinct values
  V(price)         = 200          #of distinct values
  Range(price)     = [1,50)       range of values
```

```
SELECT DISTINCT name
FROM   Harris_Teeter
```



How many tuples do we expect this query to output?

900

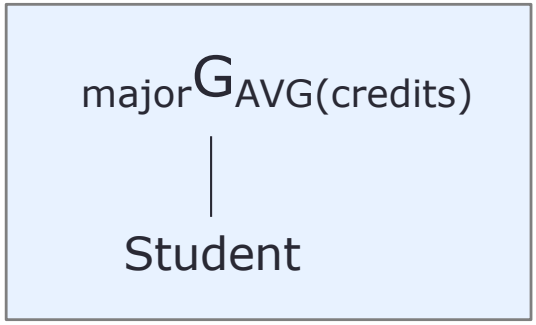
Estimation: AGGREGATE

Assume we know the following information:

Student (studId, lastName, fistName, major, credits)

```
T(Student) = 10,000          #of tuples
V(lastName) = 9,500          #of distinct values
V(major) = 10                #of distinct values
Range(credits) = [1, 126)    range of values
```

```
SELECT major, AVG(credits)
FROM Student
GROUP BY major
```



How many tuples do we expect this query to output?

10

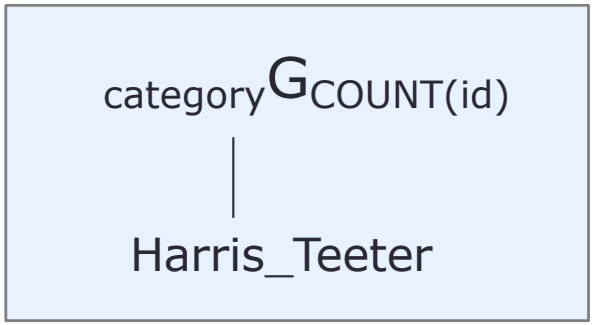
Let's Try: AGGREGATE

Let's go grocery shopping. Assume we know the following info:

```
Harris_Teeter(id, name, category, price)

  T(Harris_Teeter) = 1,000        #of tuples
  V(name)          = 900          #of distinct values
  V(category)      = 10           #of distinct values
  V(price)         = 200          #of distinct values
  Range(price)     = [1,50)       range of values
```

```
SELECT category, COUNT(id)
FROM   Harris_Teeter
GROUP BY category
```



How many tuples do we expect this query to output?

10

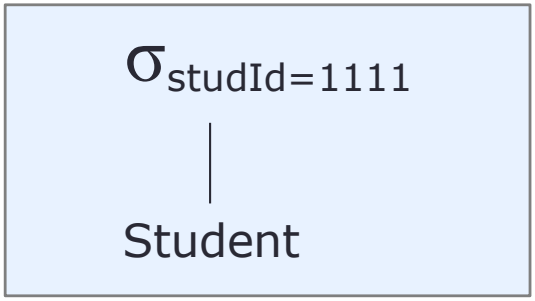
Estimation: WHERE Value

Assume we know the following information:

Student (studId, lastName, fistName, major, credits)

```
T(Student) = 10,000          #of tuples
V(lastName) = 9,500          #of distinct values
V(major) = 10                #of distinct values
Range(credits) = [1, 126)    range of values
```

```
SELECT *
FROM Student
WHERE studId = 1111
```



How many tuples do we expect this query to output?
(assume that 1111 exists)

1

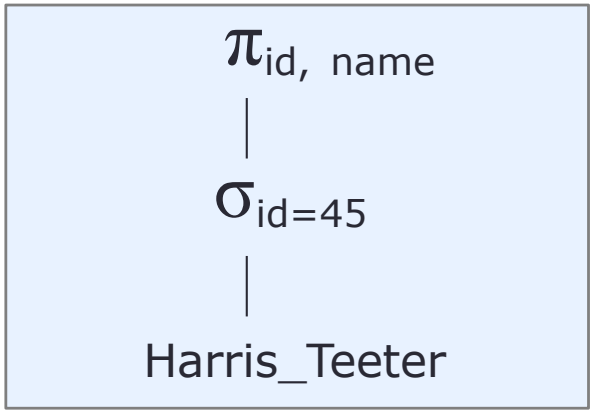
Let's Try: WHERE Value

Let's go grocery shopping. Assume we know the following info:

```
Harris_Teeter(id, name, category, price)

  T(Harris_Teeter) = 1,000        #of tuples
  V(name)          = 900          #of distinct values
  V(category)      = 10           #of distinct values
  V(price)         = 200          #of distinct values
  Range(price)     = [1,50)       range of values
```

```
SELECT id, name
FROM   Harris_Teeter
WHERE  id = 45
```



How many tuples do we expect this query to output?

1

Assume: '45' exists in the distinct values of id

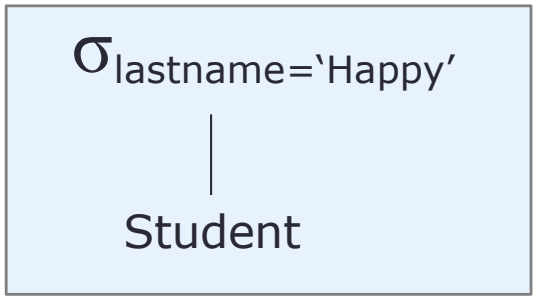
Estimation: WHERE Value

Assume we know the following information:

```
Student (studId, lastName, fistName, major, credits)

  T(Student) = 10,000          #of tuples
  V(lastName) = 9,500          #of distinct values
  V(major) = 10                #of distinct values
  Range(credits) = [1, 126)    range of values
```

```
SELECT *
FROM Student
WHERE lastname = 'Happy'
```



How many tuples do we expect this query to output?
(assume distinct values uniformly distribute; constant 'Happy' exists; without assumption, estimate is impossible)

$$T(R) * \frac{1}{V(attr)} = 10000 * \frac{1}{9500} \approx 1.05 \text{ tuples}$$

Selectivity factor

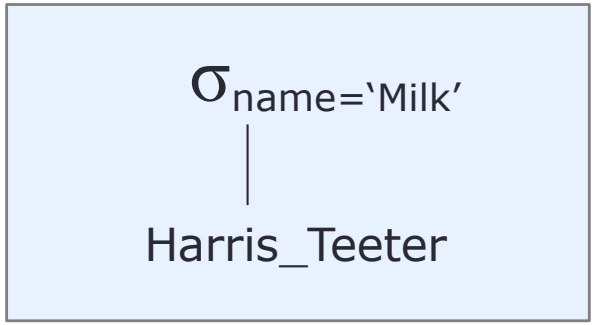
Let's Try: WHERE Value

Let's go grocery shopping. Assume we know the following info:

```
Harris_Teeter(id, name, category, price)

  T(Harris_Teeter) = 1,000        #of tuples
  V(name)          = 900          #of distinct values
  V(category)      = 10           #of distinct values
  V(price)         = 200          #of distinct values
  Range(price)     = [1,50)       range of values
```

```
SELECT *
FROM   Harris_Teeter
WHERE  name = 'Milk'
```



How many tuples do we expect this query to output?

$$T(R) * \frac{1}{V(attr)} = 1000 * \frac{1}{900} \approx 1.11 \text{ tuples}$$

Selectivity factor

Assume: 'Milk' exists in name, and distinct values uniformly distributed

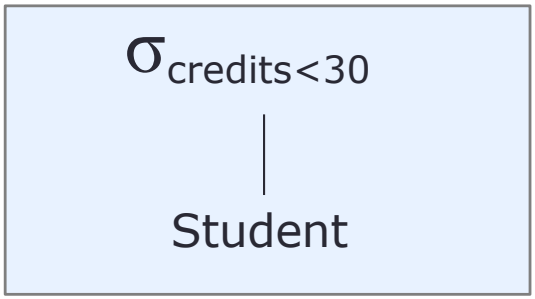
Estimation: WHERE Range

Assume we know the following information:

```
Student (studId, lastName, fistName, major, credits)

  T(Student) = 10,000          #of tuples
  V(lastName) = 9,500          #of distinct values
  V(major) = 10                #of distinct values
  Range(credits) = [1, 126)    range of values
```

```
SELECT *
FROM Student
WHERE credits < 30
```



How many tuples do we expect this query to output?
(assume uniformly distributed and continuous; without assumption, estimate is impossible)

$$T(R) * \frac{(\text{val} - \min)}{(\max - \min)} = 10000 * \frac{(30-1)}{(126-1)} \approx 2320 \text{ tuples}$$

Selectivity factor = (selection range) / (total range)

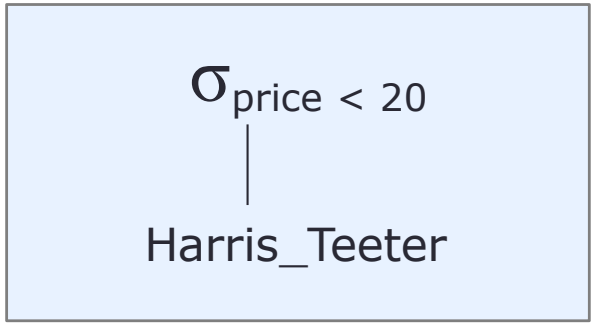
Let's Try: WHERE Range

Let's go grocery shopping. Assume we know the following info:

```
Harris_Teeter(id, name, category, price)

  T(Harris_Teeter) = 1,000        #of tuples
  V(name)          = 900          #of distinct values
  V(category)      = 10           #of distinct values
  V(price)         = 200          #of distinct values
  Range(price)     = [1,50)       range of values
```

```
SELECT *
FROM   Harris_Teeter
WHERE  price < 20
```



How many tuples do we expect this query to output?

$$T(R) * \frac{(\text{val} - \min)}{(\max - \min)} = 1000 * \frac{(20-1)}{(50-1)} \approx 387.8 \text{ tuples}$$

Selectivity factor

Assume: distinct values uniformly distributed and continuous

Estimation: AND

Assume we know the following information:

Student (studId, lastName, fistName, major, credits)

```
T(Student) = 10,000          #of tuples
V(lastName) = 9,500          #of distinct values
V(major) = 10                #of distinct values
Range(credits) = [1, 126)    range of values
```

```
SELECT *
FROM Student
WHERE credits < 30
AND lastname = 'Happy'
```

$\sigma_{\text{credits<30 AND lastname='Happy'}}$

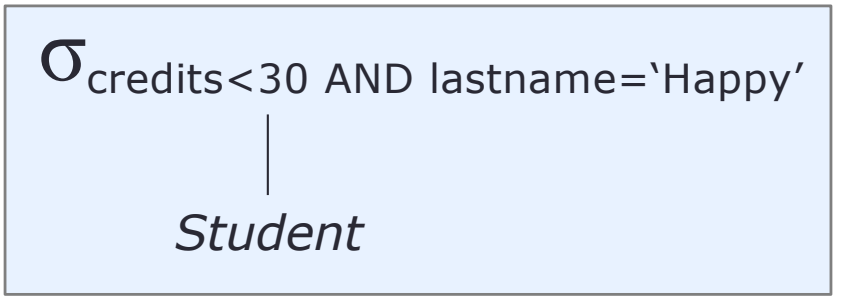
|

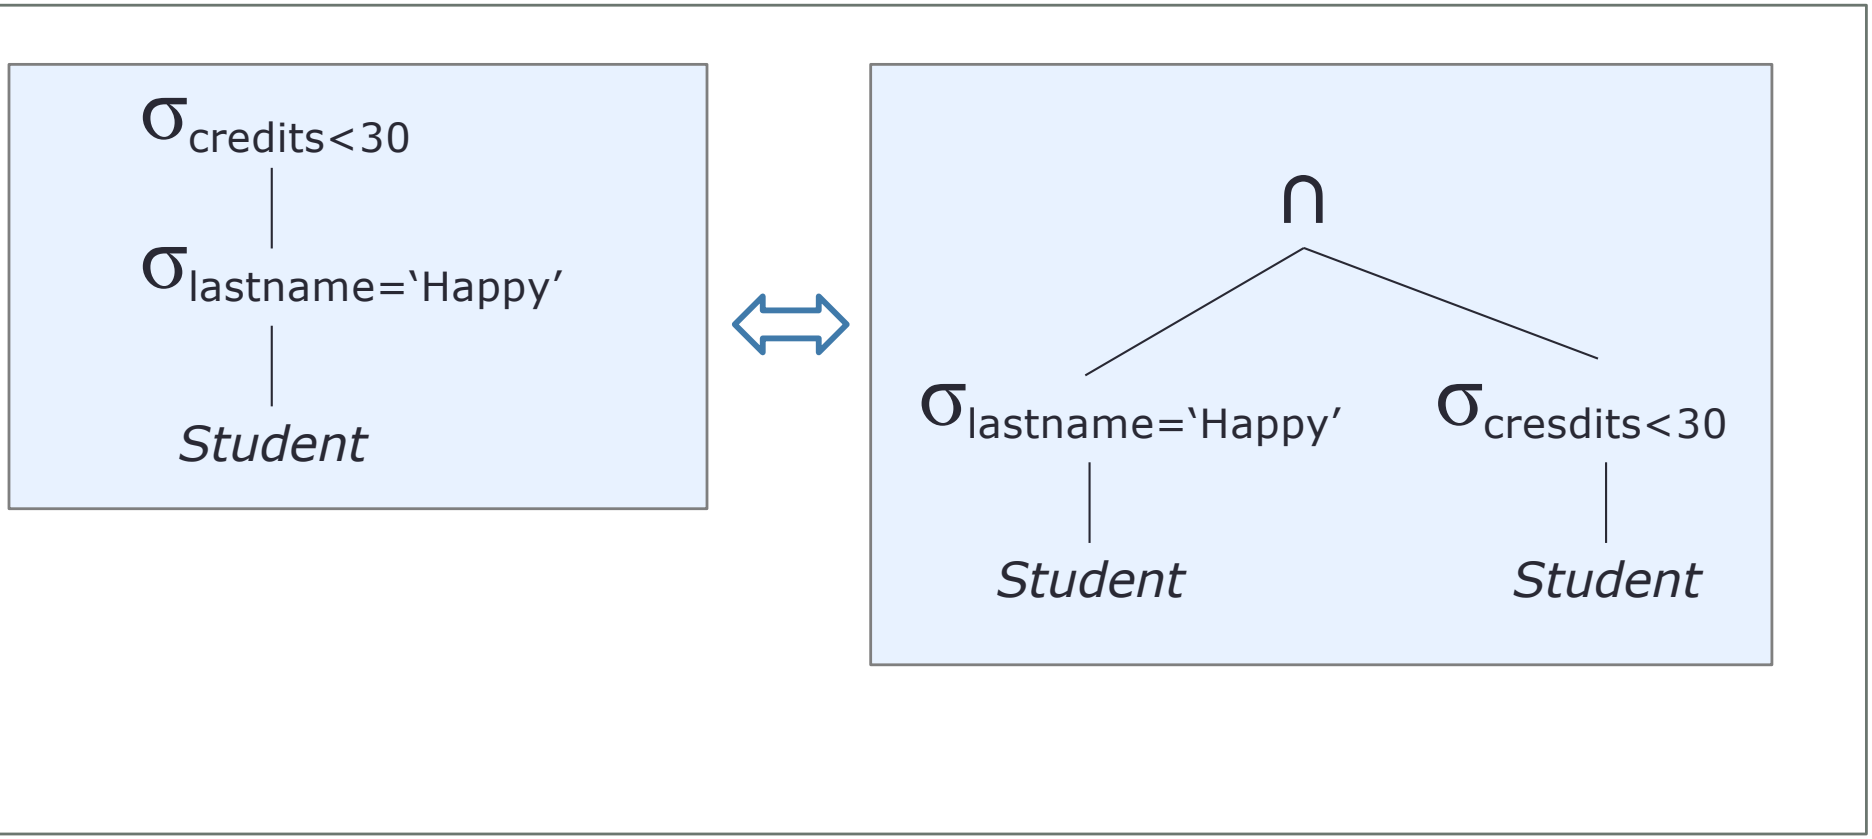
Student

How many tuples do we expect this query to output?
(assume constants exist, distinct values uniformly distributed and continuous, 'Happy' exists; without assumption, estimate is impossible)

Estimation: AND (2)

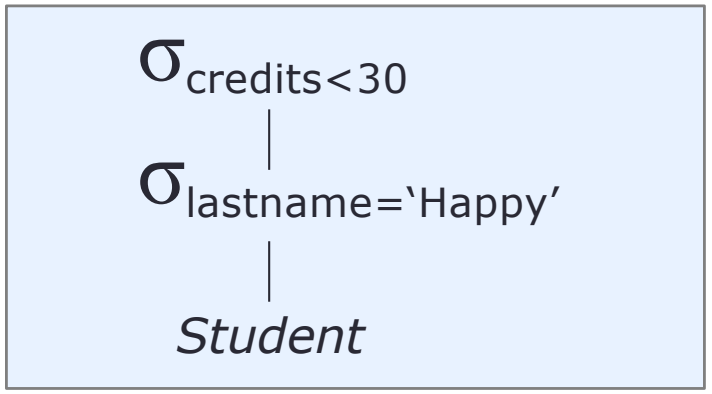
```
SELECT *
FROM Student
WHERE credits < 30
AND lastname = 'Happy'
```





Estimation: AND (3)

```
SELECT *
FROM Student
WHERE credits < 30
AND lastname = 'Happy'
```



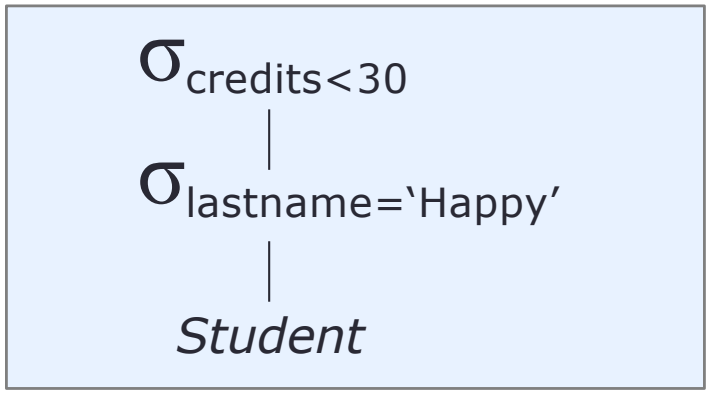
How many tuples do we expect this query to output? – hard to say

- If conditions disjoint, 0 tuple result
  - E.g. no student with lastname 'Happy' has credits <30
- If conditions independent, there will be multiple estimates
  - E.g. lastname and credits are independent
- If conditions fully overlap, take minimum of estimates
  - E.g. all students with lastname 'Happy' have credits <30

Assume independent unless you know for sure full overlap

Estimation: AND (4)

```
SELECT *
FROM Student
WHERE credits < 30
AND lastname = 'Happy'
```



How many tuples do we expect this query to output? – hard to say

- If conditions disjoint, 0 tuple result

= 0

Selectivity factor

- If conditions independent, there will be multiple estimates

≈ 10000 * ((30-1) / (126-1)) * (1/9500) ≈ 0.244 tuples

- If conditions fully overlap, take minimum of estimates

≤ 10000 * min{ (30-1) / (126-1), (1/9500) } ≈ 1.053 tuples

(assume independent unless otherwise specified --- answer: 0.244 tuples)

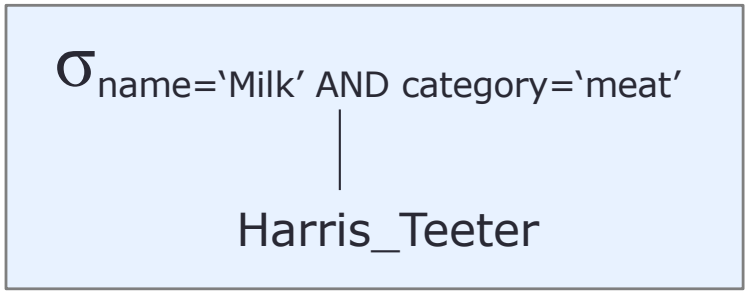
Let's Try: AND

Let's go grocery shopping. Assume we know the following info:

```
Harris_Teeter(id, name, category, price)

  T(Harris_Teeter) = 1,000      #of tuples
  V(name)          = 900        #of distinct values
  V(category)      = 10         #of distinct values
  V(price)         = 200        #of distinct values
  Range(price)     = [1,50)     range of values
```

```
SELECT *
FROM   Harris_Teeter
WHERE  name='Milk' AND
       category='meat'
```



Assume: 'Milk' exists in name, 'meat' exists in category, distinct values uniformly distributed, and conditions independent

$$T(R) * \frac{1}{V(name)} * \frac{1}{V(category)} = 1000 * \frac{1}{900} * \frac{1}{10} \approx 0.11 \text{ tuples}$$

Selectivity factor

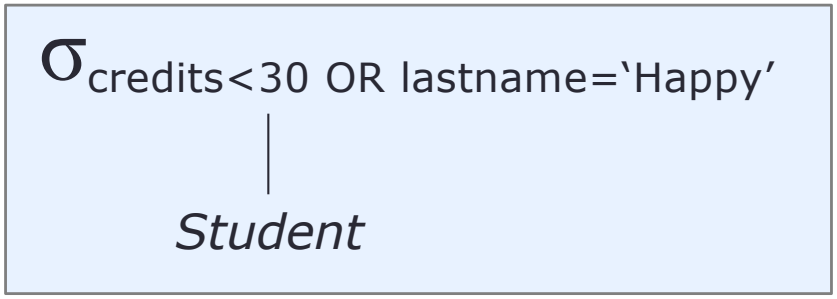
Estimation: OR

Assume we know the following information:

Student (studId, lastName, fistName, major, credits)

```
T(Student) = 10,000          #of tuples
V(lastName) = 9,500          #of distinct values
V(major) = 10                #of distinct values
Range(credits) = [1, 126)    range of values
```

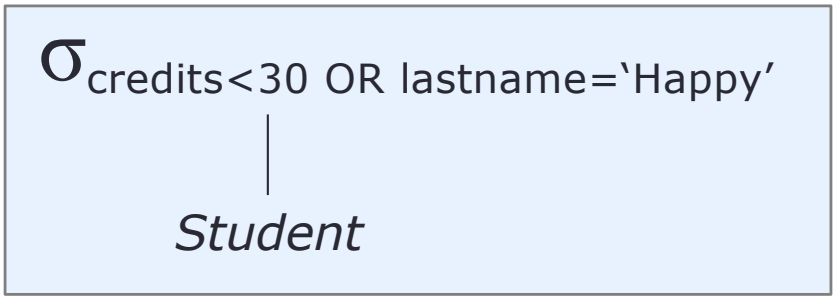
```
SELECT *
FROM Student
WHERE credits < 30
OR lastname = 'Happy'
```

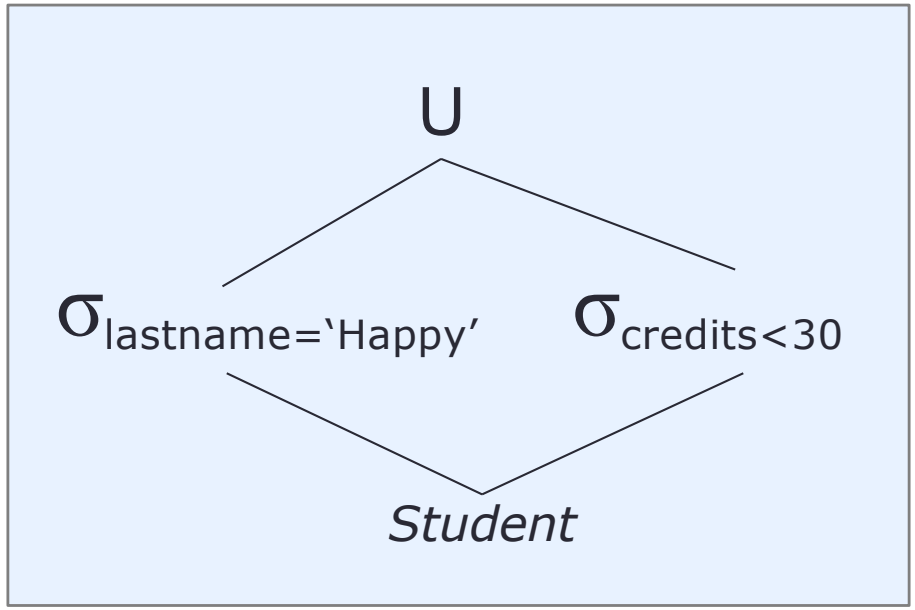


How many tuples do we expect this query to output?
(assume constants exist, distinct values uniformly distributed and continuous; without assumption, estimate is impossible)

Estimation: OR (2)

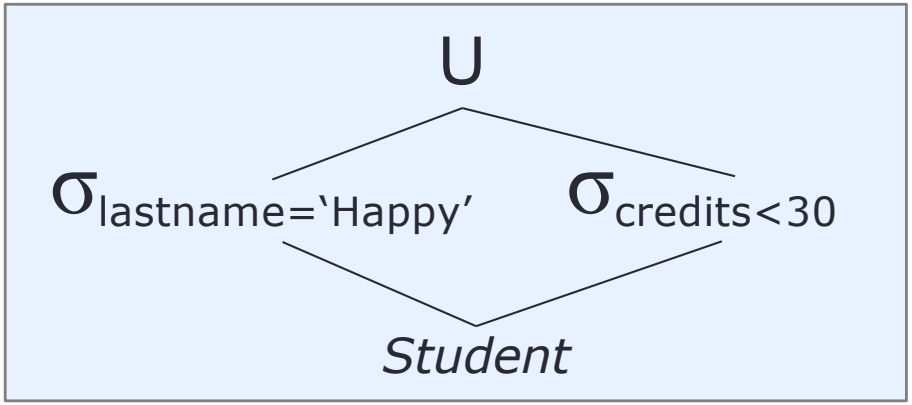
```
SELECT *
FROM Student
WHERE credits < 30
OR lastname = 'Happy'
```





Estimation: OR (3)

```
SELECT *
FROM Student
WHERE credits < 30
OR lastname = 'Happy'
```



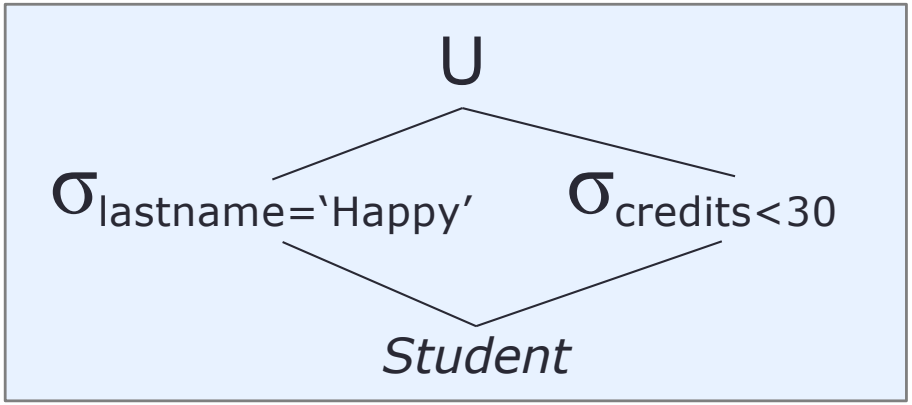
How many tuples do we expect this query to output? – hard to say

- If conditions disjoint, add estimates
  - E.g. no student with lastname 'Happy' has credits <30
- If conditions fully overlap, take maximum of estimates
  - E.g. all students with lastname 'Happy' have credits <30

Assume disjoint unless you know for sure full overlap

Estimation: OR (4)

```
SELECT *
FROM Student
WHERE credits < 30
OR lastname = 'Happy'
```



How many tuples do we expect this query to output? – hard to say

- If conditions disjoint, add estimates

≤ 10000 * ((30-1) / (126-1)) + (10000 * 1/9500) ≈ 2321 tuples

- If conditions fully overlap, take maximum of estimates

≥ 10000 * max{ ((30-1) / (126-1)), (1/9500) } ≈ 2320 tuples

(assume disjoint unless otherwise specified --- answer: 2321 tuples)

Selectivity factor

Let's Try: OR

Let's go grocery shopping. Assume we know the following info:

```
Harris_Teeter(id, name, category, price)

  T(Harris_Teeter) = 1,000        #of tuples
  V(name)          = 900          #of distinct values
  V(category)      = 10           #of distinct values
  V(price)         = 200          #of distinct values
  Range(price)     = [1,50)       range of values
```

```
SELECT *
FROM   Harris_Teeter
WHERE  name='Milk' OR
       category='meat'
```

$\sigma_{\text{name='Milk' AND category='meat'}}$

|

Harris_Teeter

Assume: 'Milk' exists in name, 'meat' exists in category, distinct values uniformly distributed, and conditions disjoint

$$\leq \left\lceil T(R) * \frac{1}{V(name)} \right\rceil + \left\lceil T(R) * \frac{1}{V(category)} \right\rceil = \left\lceil 1000 * \frac{1}{900} \right\rceil + \left\lceil 1000 * \frac{1}{10} \right\rceil$$

$$\approx 101.11 \text{ tuples}$$

Selectivity factor

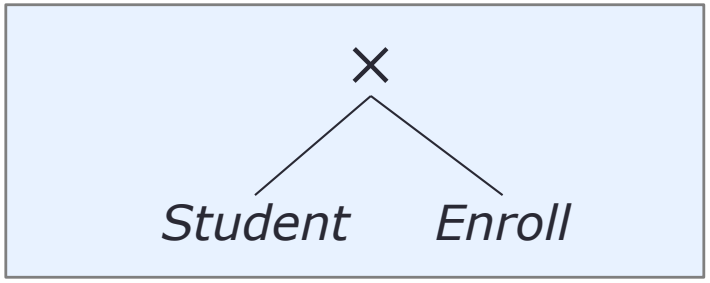
Estimation: Cartesian Product

Assume we know the following information:

```
Student (studId, lastName, fistName, major, credits)
  T(Student) = 10,000                    #of tuples
  V(lastName) = 9,500                    #of distinct values
  V(major) = 10                          #of distinct values
  Range(credits) = [1, 126)              range of values

Enroll (studId, classNumber, grade)
  T(Enroll) = 50,000                     #of tuples
  V(studId) = 10,000                     #of distinct values
  V(classNumber) = 200                   #of distinct values
```

```
SELECT *
FROM Student, Enroll
```



How many tuples do we expect this query to output?

T(Student) * T(Enroll) = 10000 * 50000 tuples

No selectivity factor (because no WHERE clause applied)

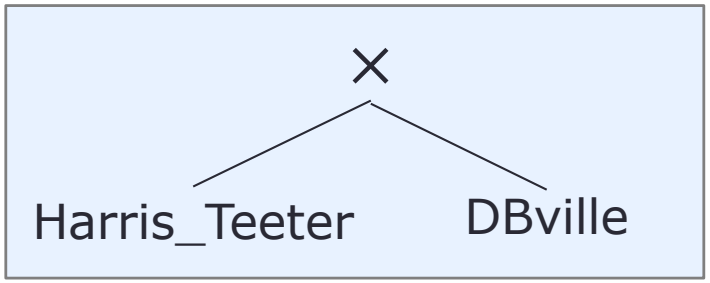
Let's Try: Cartesian Product

Let's go grocery shopping. Assume we know the following info:

```
Harris_Teeter(id,name,category,price)
  T(Harris_Teeter) = 1,000
  V(name)          = 900
  V(category)      = 10
  V(price)         = 200
  Range(price)     = [1,50)
```

```
DBville(id,dname,shelf,cost)
  T(DBville)   = 2,000
  V(dname)     = 1,900
  V(shelf)     = 12
  V(cost)      = 500
```

```
SELECT *
FROM   Harris_Teeter, DBville
```



How many tuples do we expect this query to output?

T(Harris_Teeter) * T(DBville) = 1,000 * 2,000 = 2,000,000 tuples

No selectivity factor (because no WHERE clause applied)

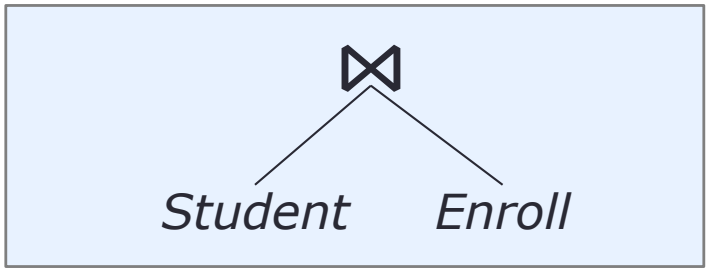
Estimation: JOIN

Assume we know the following information:

```
Student (studId, lastName, fistName, major, credits)
  T(Student) = 10,000                    #of tuples
  V(lastName) = 9,500                    #of distinct values
  V(major) = 10                          #of distinct values
  Range(credits) = [1, 126)              range of values

Enroll (studId, classNumber, grade)
  T(Enroll) = 50,000                     #of tuples
  V(studId) = 10,000                     #of distinct values
  V(classNumber) = 200                   #of distinct values
```

```
SELECT *
FROM Student
NATURAL JOIN Enroll
```



How many tuples do we expect this query to output?

≤ T(Student) * T(Enroll)

≤ 10000 * 50000 tuples

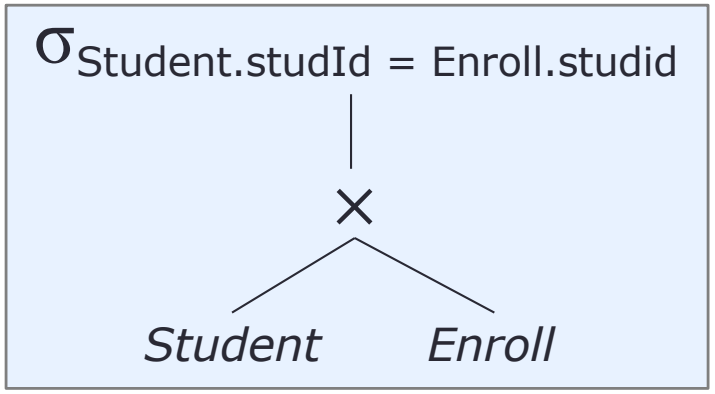
Can we do better?

Estimation: JOIN (2)

1. Start with Cartesian product

```
SELECT *
FROM Student, Enroll
WHERE Student.studId = Enroll.studId
```

T(Student) * T(Enroll)



2. Suppose there are `studId` in both relations that match

3. How many times does `sid0` occur? (assume `sid0` is studentId)

   How many tuples do we expect from

σStudent.studId=sid0 AND Enroll.studId=sid0

Selectivity factor = $\frac{1}{V(Student, studId)} * \frac{1}{V(Enroll, studId)}$

Estimation: JOIN (3)

4. How many distinct values of `sid0s` exist in the join?
   - If no overlap

     0
   - If full overlap

     ≤ min{ V(Student, studId), V(Enroll, studId) }

Assume full overlap
(~ one is a subset of the other)

5. Multiply (1), (3), and (4)

$$\frac{\mathrm{T(Student)} * \mathrm{T(Enroll)}}{V(Student, studId) * V(Enroll, studId)} * \min\{\mathrm{V(Student, studId)}, \mathrm{V(Enroll, studId)}\}$$

Simplify to

$$\frac{\mathrm{T(Student)} * \mathrm{T(Enroll)}}{\max\{\mathrm{V(Student, studId)}, \mathrm{V(Enroll, studId)}\}}$$

Estimation: JOIN (4)

Assume we know the following information:

```
Student (studId, lastName, fistName, major, credits)
  T(Student) = 10,000                    #of tuples
  V(lastName) = 9,500                    #of distinct values
  V(major) = 10                          #of distinct values
  Range(credits) = [1, 126)              range of values

Enroll (studId, classNumber, grade)
  T(Enroll) = 50,000                     #of tuples
  V(studId) = 10,000                     #of distinct values
  V(classNumber) = 200                   #of distinct values
```

$$\frac{T(\text{Student}) * T(\text{Enroll})}{\max\{V(\text{Student}, \text{studId}), V(\text{Enroll}, \text{studId})\}} = \frac{10000 * 50000}{\max\{10000, 10000\}} = 50000 \text{ tuples}$$

Since we assume full overlap of `studIds` between `Student` and `Enroll`, we only need the `studIds` of the smaller relation

Let's Try: JOIN

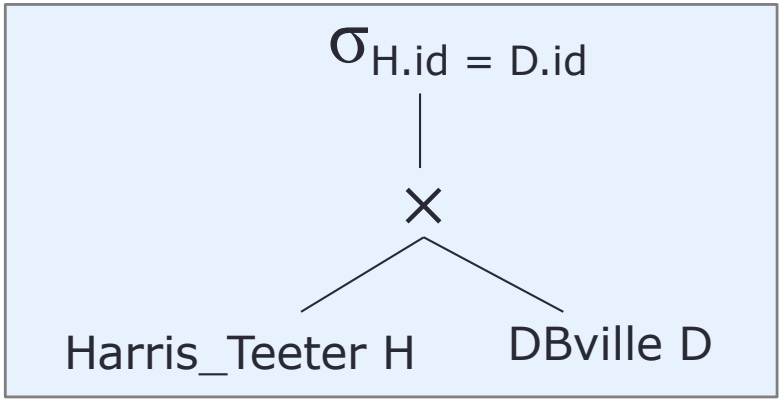
Let's go grocery shopping. Assume we know the following info:

```
Harris_Teeter(id,name,category,price)
  T(Harris_Teeter) = 1,000
  V(name)          = 900
  V(category)      = 10
  V(price)         = 200
  Range(price)     = [1,50)
```

```
DBville(id,dname,shelf,cost)
  T(DBville)   = 2,000
  V(dname)     = 1,900
  V(shelf)     = 12
  V(cost)      = 500
```

```
SELECT *
FROM   Harris_Teeter H
NATURAL JOIN DBville D
```

Assume full overlap of `id` between the relations, thus need the `ids` of the smaller relation



How many tuples do we expect this query to output?

$$\frac{T(\text{Harris\_Teeter}) * T(\text{DBville})}{\max\{V(\text{Harris\_Teeter}, \text{id}), V(\text{DBville}, \text{id})\}} = \frac{1000 * 2000}{\max\{1000, 2000\}} = 1000 \text{ tuples}$$

Let's Try: JOIN on Attr

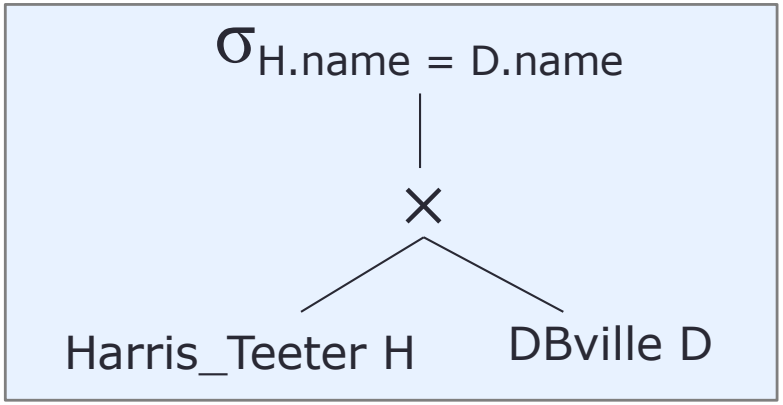
Let's go grocery shopping. Assume we know the following info:

```
Harris_Teeter(id,name,category,price)
  T(Harris_Teeter) = 1,000
  V(name)          = 900
  V(category)      = 10
  V(price)         = 200
  Range(price)     = [1,50)
```

```
DBville(id,dname,shelf,cost)
  T(DBville)   = 2,000
  V(dname)     = 1,900
  V(shelf)     = 12
  V(cost)      = 500
```

```
SELECT *
FROM   Harris_Teeter H, Dbville D
WHERE  H.name = D.dname
```

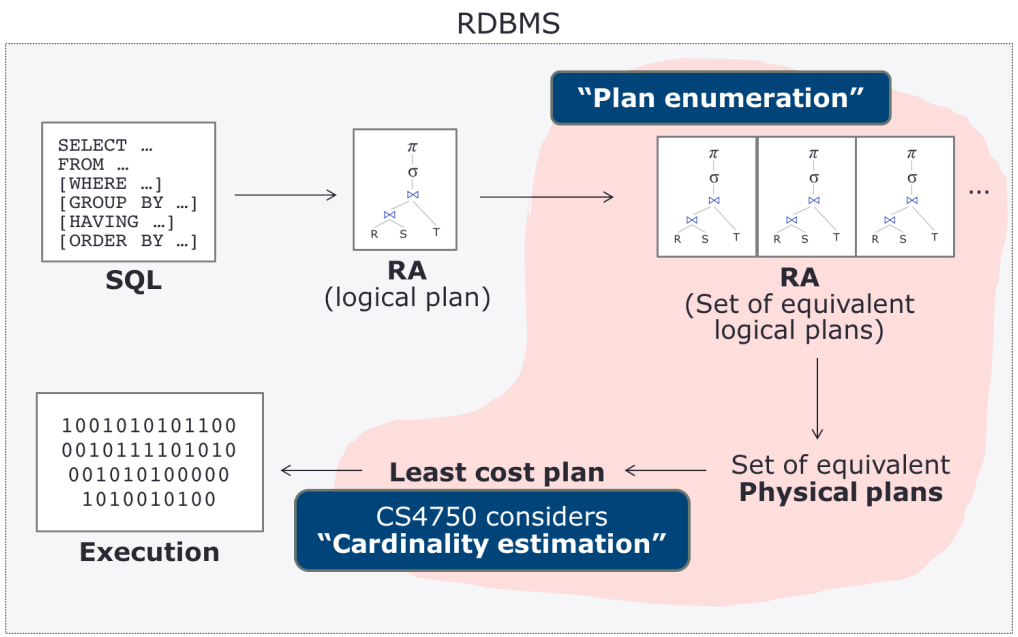
Assume full overlap of name and dname



How many tuples do we expect this query to output?

$$\frac{T(\text{Harris\_Teeter}) * T(\text{DBville})}{\max\{V(\text{Harris\_Teeter}, \text{name}), V(\text{DBville}, \text{dname})\}} = \frac{1000 * 2000}{\max\{900, 1900\}} \approx 1053 \text{ tuples}$$

Wrap-Up



- Cardinality estimation
- Real RDBMS uses sophisticated cost model
- Making inappropriate assumptions to estimate cardinality may lead to:
  - Inaccurate estimates
  - Optimization selects a slow plan
  - Slow query execution
- Be careful and document your assumptions

What's next?

- Indexing
