# **Distributed Database**

#### CS 4750 Database Systems

[Silberschatz, Korth, Sudarshan, "Database System Concepts," 7<sup>th</sup> Edition, Ch. 21] [Pattamsetti, "Distributed Computing in Java 9," Ch. 6] [Ricardo and Urban, "Databases illuminated," 3<sup>rd</sup> ed., Ch. 10]

© Praphamontripong

#### Recap

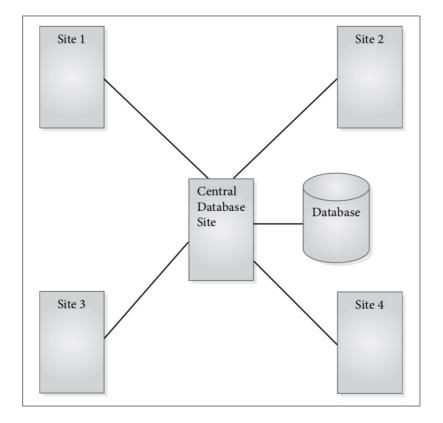

- Core Database Systems
  - Database design: E-R, Normalization
  - Database programming
  - SQL and RA
  - Database security
  - Indexing
  - Query cost estimation (part of optimization)
  - Transactions ACID
- Distributed relational databases CAP
- Non-relational database: NoSQL BASE

Today

### **Centralized Databases**

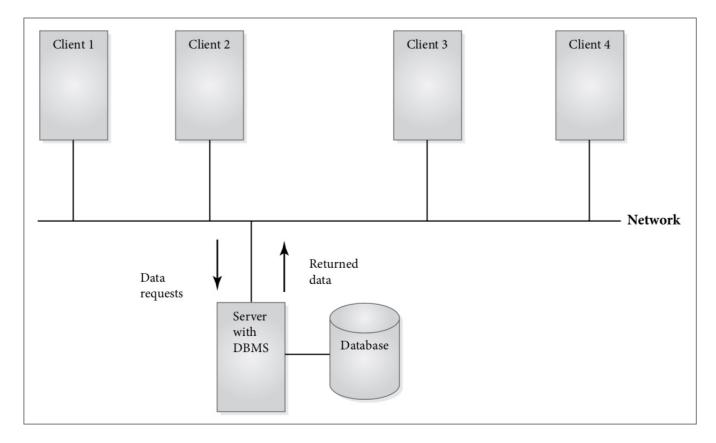

#### A centralized database used by multiple sites

[Ref: Ricardo and Urban, "Databases Illuminated," 3rd ed., p. 441]

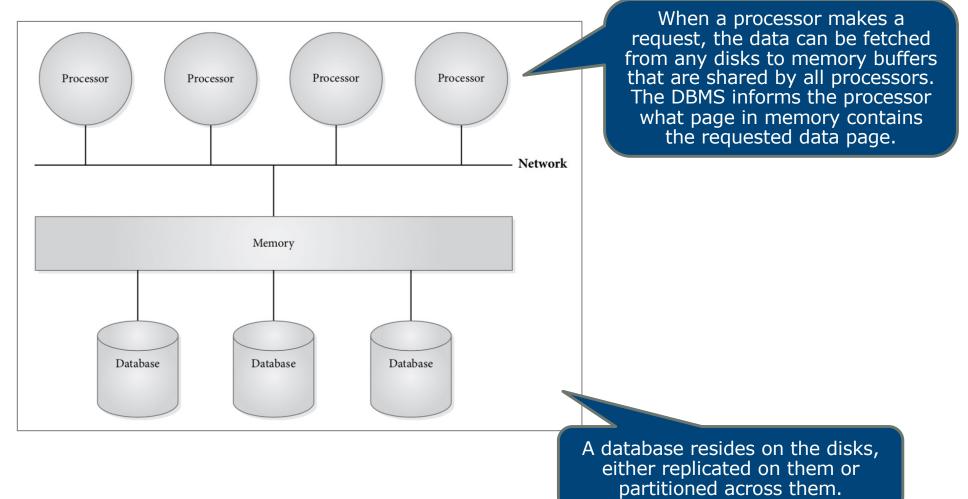

### **Centralized Databases**

#### A centralized database used in a client-server environment

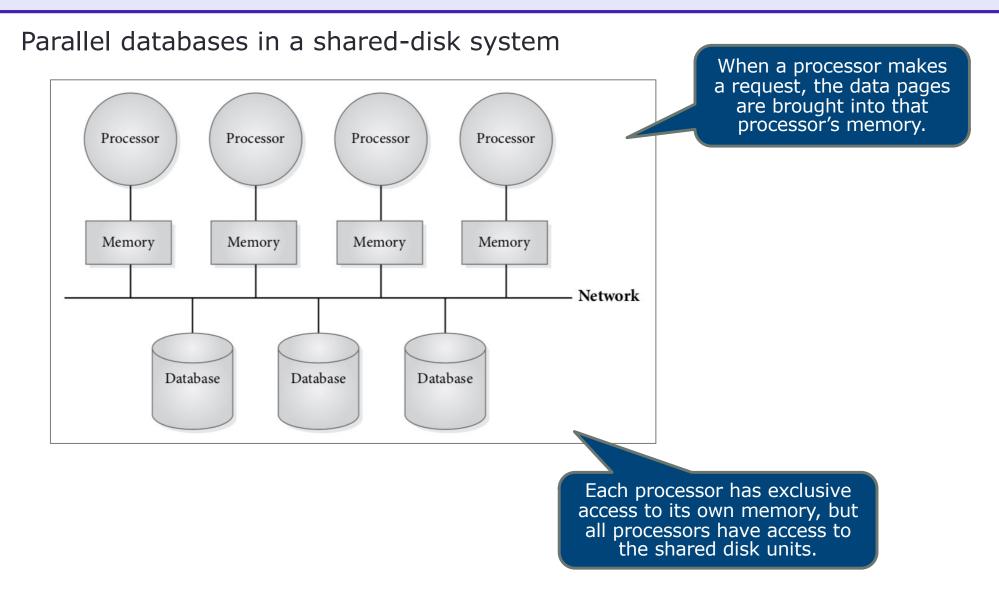

[Ref: Ricardo and Urban, "Databases Illuminated," 3rd ed., p. 442]

#### Parallel databases in a shared-memory system

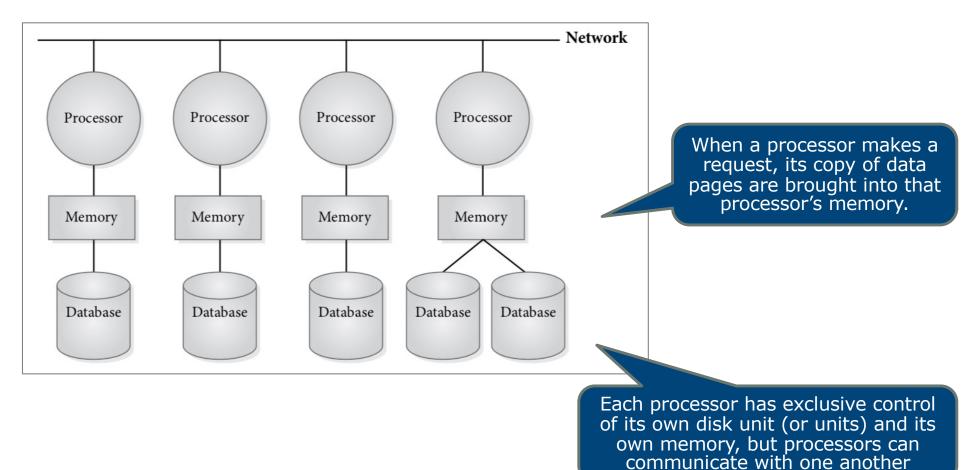

#### [Ref: Ricardo and Urban, "Databases Illuminated," 3<sup>rd</sup> ed., p. 443]

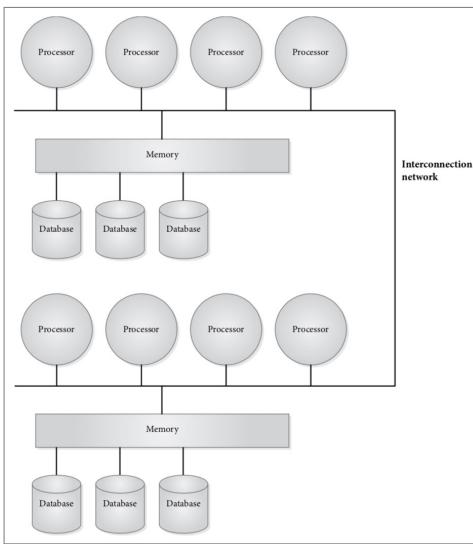

[Ref: Ricardo and Urban, "Databases Illuminated," 3<sup>rd</sup> ed., p. 444]

#### Parallel databases in a shared-nothing system

[Ref: Ricardo and Urban, "Databases Illuminated," 3<sup>rd</sup> ed., p. 444]

#### Parallel databases in a hierarchical or cluster system

A system is made up of nodes that are shared-memory. The nodes are connected by an interconnection network.

The systems shared only communications with one another; making the overall inter-system architecture shared-nothing

Parallel databases – improve performance by executing operations in parallel on various devices, less focus on database storage

[Ref: Ricardo and Urban, "Databases Illuminated," 3rd ed., p. 445]

# **Scaling Issues in Centralized DB**

- As a DB gets bigger, we try to scale a DB server until a DB become bottleneck.
- One way to solve the performance issues is to change from a centralized DB to distributed DBs.

# **Distributed Database (DDB)**

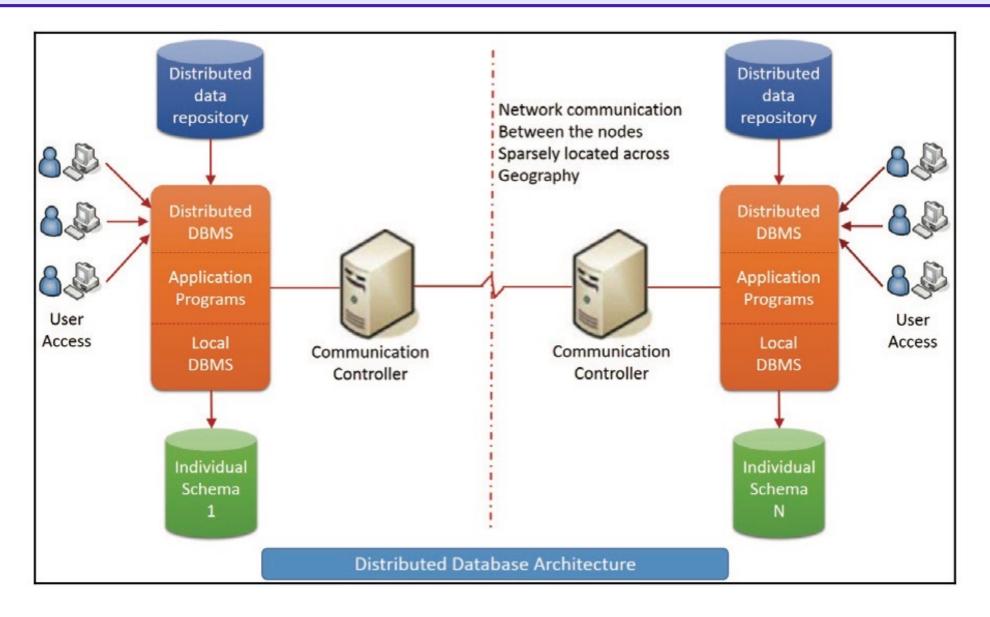

- A collection of multiple, logically interconnected databases that are physically distributed over a computer network on different sites
- Data are physically stored across multiple sites, managed by a DBMS that is independent of the other site
- Data at any site available to users at other sites
- Sites may be far apart, linked by some forms of telecommunication lines (secure lines or Internet)
- Sites that are close together may be linked by a local area network (LAN)

Distributed databases – focus on database storage and location transparency

#### Distributed Database Management System (DDBMS)

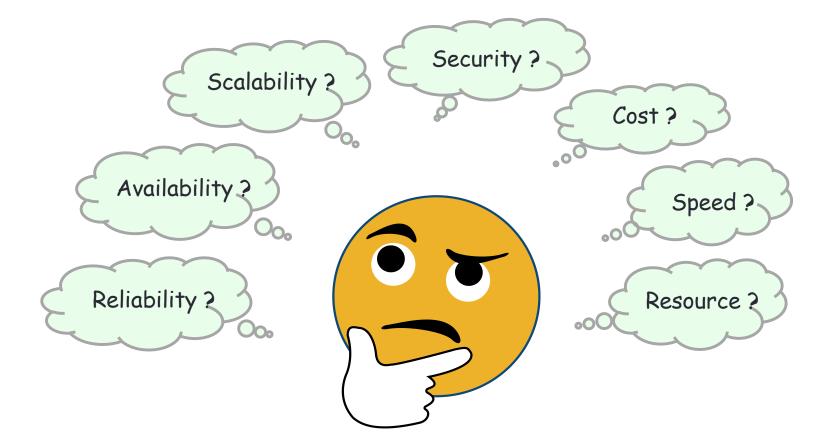

- A centralized software system that manages the DDB
- Synchronizes the databases periodically
- Provides an access mechanism that makes the distribution transparent to the users (as if it were all stored in a single location)
- Ensures that the data modified at any remote site is universally updated
- Supports a huge number of users simultaneously
- Maintains data integrity of the databases

### **Distributed Database Architecture**

Why do we need distributed databases? Isn't a centralized database enough?

### Challenges

- Security: due to the Internet usage
- Consistency issues: databases must be synchronized periodically to ensure data integrity
- Increased storage requirements: due to replication of databases
- Multiple location access: transactions may access data at one or more sites

# **Distributed Strategies**

Based on the organizational needs and information split and exchange requirements, the distributed database environment can be designed in two ways:

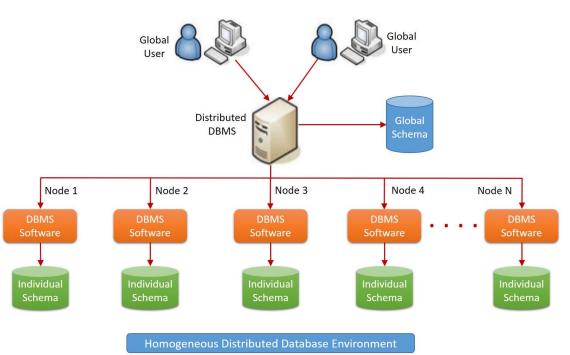

#### Homogeneous

Use the same DBMS for all database nodes that take part in the distribution

#### Heterogeneous

 May use a diverse DBMS for some of the nodes that take part in the distribution

## **Homogeneous Distributed DB**

- Information is distributed between all the nodes
- The same DBMS and schema are used across all the databases
- The distributed DBMS controls
   all information
- Every global user must access the information from the same global schema controlled by the distributed DBMS
- A combination of all the individual DB schemas makes the global schema

# **Heterogeneous Distributed DB**

- Information is distributed between all the nodes
- Different DBMS and schemas may be used across the databases
- Local users (interacting with one of the individual database) can access the corresponding DBMS and schema
- Users who want to access the global information can communicate with the distributed DBMS, which has a global schema (a combination of all the individual DB schemas)

# **Distributed DB Setup Method**

- The process of setting up the distributed DB environment involves a thorough analysis and design
- Ongoing and future information maintenance must be determined
  - Synchronous: information across all nodes should be kept in sync all the time
  - Asynchronous: information is replicated at multiple nodes to make it available for other nodes
- Once the analysis for a specific distributed DB environment is made, the setup can be performed in one of the following ways:
  - Replication
  - Fragmentation/partitioning (horizontal or vertical)
  - Hybrid setup

## Replication

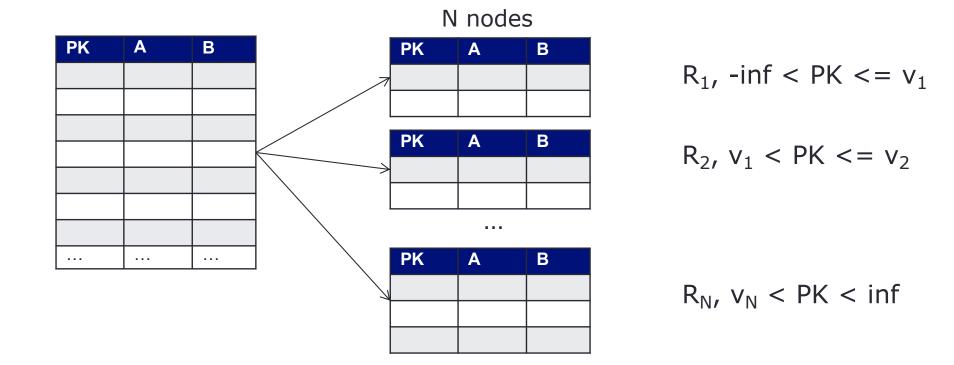

- Maintain multiple copies of the database instances, stored in different sites
- Easy and minimum risk process as the information is copied from one instance to another without a logical separation
- Each individual node has the complete information
- Efficient in accessing the information without having network traversals and reduces the risk of network security
- Fast retrieval
- Increase fault tolerance
- Require more storage space
- Take longer to synchronize all the nodes when the information across all the nodes needs to be updated

# **Fragmentation (or Partition)**

- One copy of each data item, distributed across nodes
- Split a database into disjoint fragments (or parts)
- Fragments can be
  - Vertical table subsets (formed by RA projection)
  - Horizontal subsets (formed by RA selection)

# **Horizontal Fragmentation**

- Splitting the rows of a table (or a relation between two or more nodes, containing databases) to form a distributed database – "split by region"
- Each individual database has a set of rows that belong to the table or relation that belongs to the specific database

#### **Example: Horizontal Fragmentation**

stuld	lastName	firstName	major	credits	
S1001	Smith	Tom	History	90	
S1002	Chin	Ann	Math	36	
S1005	Lee	Perry	History	3	
S1010	Burns	Edward	Art	63	K
S1013	McCarthy	Owen	Math	0	
S1015	Jones	Mary	Math	42	1
S1020	Rivera	Jane	CSC	15	

 $\sigma_{major="Math"}$  (students)

	stuld	lastName	firstName	major	credits
7	S1002	Chin	Ann	Math	36
	S1013	McCarthy	Owen	Math	0
	S1015	Jones	Mary	Math	42

#### $\sigma_{major="History"}$ (students)

	stuld	lastName	firstName	major	credits
1	S1001	Smith	Tom	History	90
	S1005	Lee	Perry	History	3

#### $\sigma_{major="Art"}$ (students)

$\setminus$	stuld lastName		firstName	major	credits	
7	S1010	Burns	Edward	Art	63	

#### $\sigma_{major="CSC"}$ (students)

. . .

stuld lastName		firstName	major	credits	
S1020	Rivera	Jane	CSC	15	

[Example adapted from Ricardo and Urban, "Databases Illuminated," fragmentation example, p. 452] - this example has been simplified

## **Horizontal Fragmentation**

- The information access is efficient
- Best if partitions are uniform
- Optimal performance as the local data are only stored in a specific database
- Allow parallel processing on fragments
- More secure as the information belonging to the other location is not stored in the database
- If a user wants to access some of the other nodes or a combination of node information, the access latency varies.
- If there is a problem with a node or a network, the information related to that node becomes inaccessible to the users

# **Practice / Thought Questions**

Assume that a chain of computer stores that sells computer, components, and parts uses the following global schema for a relational database that keeps information about items at each store:

Item(<u>itemNo</u>, itemName, supplier, unitCost)
Store(<u>storeName</u>, address, manager, telephone)
Stock(<u>itemNo</u>, <u>storeName</u>, qtyOnHand, qtyOnOrder, reorderPoint)

The company has 20 stores that stock about 15,000 different items. Each item comes from only one supplier, but there are different suppliers for different items.

The database keeps track of what items are in what store, what items have been reordered at each store, and the reorder point (which is the number of items that is the minimum each store wishes to keep in stock).

When the quantity on hand falls to the reorder point, a new order is placed, unless the item has already been reordered.

Each store serves customers in its own geographical area, but if an item is out of stock, the manager can obtain the item from another store.

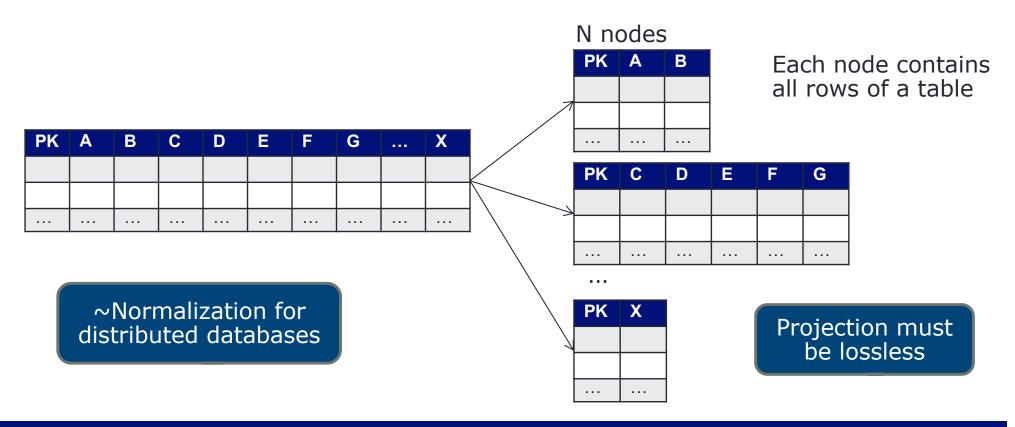

All information is currently stored in a central database. The company wishes to design a distributed database system to make operations more efficient.

Discuss in your group. Suggest how the database should be "horizontally" fragmented.

[Adapted from Ricardo and Urban, "Databases Illuminated," p. 474]

# **Vertical Fragmentation**

- (aka normalization process in distributed database setup)
- Splitting the columns of a table (or a relation between two or more nodes, containing databases) to form a distributed database while keeping a copy of the base column (primary key) to uniquely identifying each record – "split by purpose"

#### **Example: Vertical Fragmentation**

			stuld	lastName	firstName	major	credits			
			S1001	Smith	Tom	History	90			
			S1002	Chin	Ann	Math	36			
			S1005	Lee	Perry	History	3			
			S1010	Burns	Edward	Art	63			
			S1013	McCarthy	Owen	Math	0			lotice stuId in
			S1015	Jones	Mary	Math	42			all fragments
			S1020	Rivera	Jane	CSC	15			
$\pi_{stuId, lastName, firstName}(students)$ $\pi_{stuId, major}(students)$ $\pi_{stuId, credits}(students)$										
	stuld	lastName	firstNam	e	stuld	major		stuld	credits	
	S1001	Smith	Tom		S1001	History		S1001	90	
	S1002	Chin	Ann		S1002	Math		S1002	36	
	S1005	Lee	Perry		S1005	History		S1005	3	
Γ	S1010	Burns	Edward		S1010	Art		S1010	63	
	S1013	McCarthy	Owen		S1013	Math		S1013	0	
Γ	S1015	Jones	Mary		S1015	Math		S1015	42	
Γ	S1020	Rivera	Jane		S1020	CSC		S1020	15	
										]

[Example adapted from Ricardo and Urban, "Databases Illuminated," fragmentation example, p. 452] - this example has been simplified

# **Vertical Fragmentation**

- Appropriate if each of the organizational units located in different geographies have separate operations
- Partition based on behavior and function that each node performs
- Best if partitions are uniform
- Part of the tuple is stored where it is most frequently accessed
- Allow parallel processing on fragments
- Poorly chosen columns to split can lead to node bottleneck
- The aggregation of the data involves complex queries with joins across the location database, as no replication is made for nonprimary keys

# **Practice / Thought Questions**

Assume that a chain of computer stores that sells computer, components, and parts uses the following global schema for a relational database that keeps information about items at each store:

Item(<u>itemNo</u>, itemName, supplier, unitCost)
Store(<u>storeName</u>, address, manager, telephone)
Stock(<u>itemNo</u>, <u>storeName</u>, qtyOnHand, qtyOnOrder, reorderPoint)

The company has 20 stores that stock about 15,000 different items. Each item comes from only one supplier, but there are different suppliers for different items.

The database keeps track of what items are in what store, what items have been reordered at each store, and the reorder point (which is the number of items that is the minimum each store wishes to keep in stock).

When the quantity on hand falls to the reorder point, a new order is placed, unless the item has already been reordered.

Each store serves customers in its own geographical area, but if an item is out of stock, the manager can obtain the item from another store.

All information is currently stored in a central database. The company wishes to design a distributed database system to make operations more efficient.

#### Discuss in your groups. Suggest how the database should be "vertically" fragmented.

[Adapted from Ricardo and Urban, "Databases Illuminated," p. 474]

## **Correctness of Fragmentation**

#### Completeness

 Decomposition of a relation R into R<sub>1</sub>, R<sub>2</sub>, ..., R<sub>n</sub> is complete if and only if each data item in R can also be found in some R<sub>i</sub>

#### Reconstruction

• If a relation *R* is decomposed into *R*<sub>1</sub>, *R*<sub>2</sub>, ..., *R*<sub>n</sub>, reconstructing *R*<sub>1</sub>, *R*<sub>2</sub>, ..., *R*<sub>n</sub> should result in the original *R* 

#### Disjointness

 If a relation R is decomposed into R<sub>1</sub>, R<sub>2</sub>, ..., R<sub>n</sub> and data item d is in R<sub>i</sub>, then d should not be in any other fragment R<sub>j</sub> where i <> j

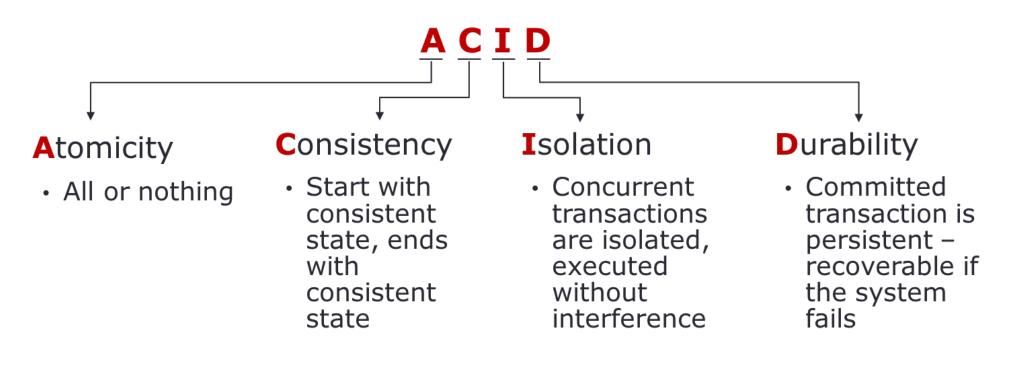

# **Hybrid Setup**

- Involve a combination of replication and fragmentation
- Relation is partitioned into several fragments
- Some information is replicated across the database nodes
- Data administrators play a crucial role to choose the right combination to ensure data integrity and security

revisit

# **RDBMS and ACID Properties**

Four properties of transactions that a DBMS follows to handle concurrent access while maintaining consistency

ACID work in a centralized database system, not in a distributed database system

# **Threats on ACID Properties**

- While distributed database system has many advantages, it imposes a threat on ACID properties
- Consistency in database (ACID)
  - Database relies on a set of integrity constraints
  - DBMS executes each transaction to ensure Atomicity and Isolation and thus maintaining a consistent state
- Consistency in distributed database system with replication
  - Strong consistency:

Final state from a schedule with read and write operations on a replicated object Final state from a schedule on a single copy of the object with order of operations from a single site preserved

• Weak consistency: (several forms)

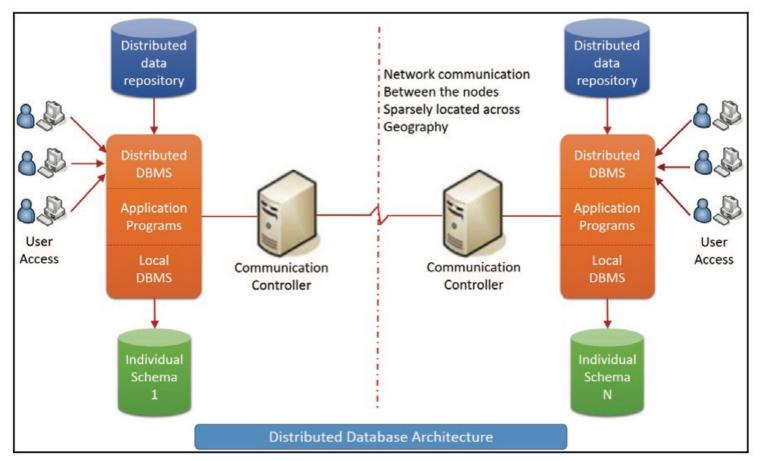

### **CAP Theorem**

- **Consistency** -- All copies (across nodes) have the same value
- **Availability** -- System can still function even if some nodes fail
- **Partition tolerance** -- System can function even if communication between nodes (the partitions reside) fails
  - Network can break into two or more parts, each with active systems that communicate with the other parts
- Must have **exactly two** of the three properties for any system
- Very large system will partition by default, thus choose one of consistency or availability
  - Traditional database choose consistency
  - Most web apps choose availability (except some specific/important parts such as order/payment processing)

# **CAP: Example Combination**

#### Consistency/Partition tolerance

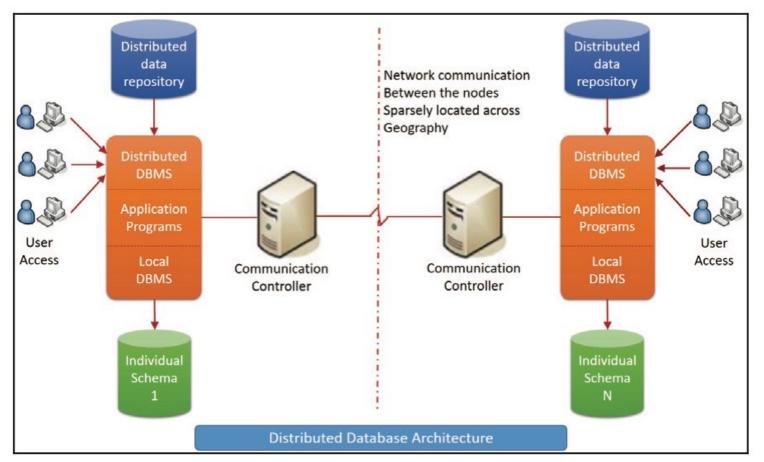

• Queries are executed on one site. Then they are passed to all other sites, which then execute the queries.

# **CAP: Example Combination**

#### Availability/Partition tolerance

 Each site provides services independently. No impact if a network goes down or other sites fail. – resulting in inconsistent DBs

## **CAP: Example Combination**

#### Consistency/Availability

• Each site provides services independently as its own system.

### **Threats on CAP**

- Only two of the three properties are guarantees:
  - Consistency every read receives the most recent write or an error
  - Availability every request must respond with a non-error
  - Partition tolerance continued operation in presence of dropped or delayed message
- Distributed RDBMS partition tolerance + consistency

Intended to be highly consistent – but may sacrifice some consistency to boost availability

• NoSQL systems – partition tolerance + availability

Intended to be highly available – but may sacrifice some availability to boost consistency

With the growth of data  $\rightarrow$  achieving CAP is very difficult. Instead of using ACID or CAP, use BASE (a more relaxed set of properties)

# **BASE Consistency Model**

- With the enormous growth in data, achieving ACID or CAP becomes very difficult.
- A more relaxed set of properties is **BASE**
- **Basically Available, Soft state, Eventually consistent**

- Key idea:
  - Databases may not all be in the same state at the same time ("soft state")
  - After synchronization is complete, the state will be consistent

# Wrap-Up

• Distributed Database Systems  $\rightarrow$  database scaling

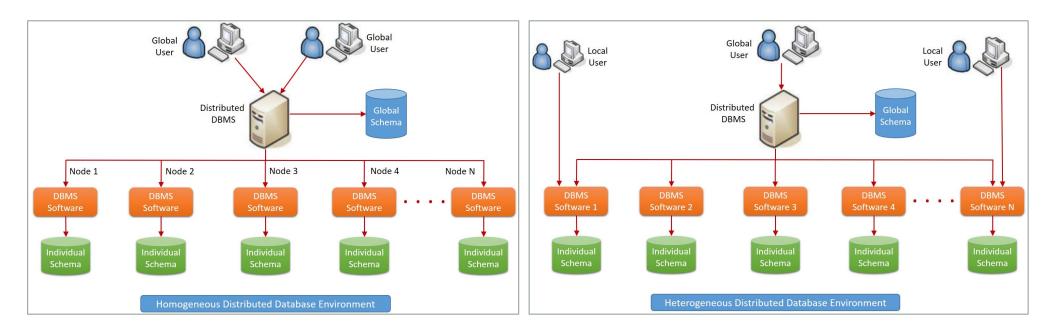

#### Replication

- Multiple copies of each database partition
- Improves fault tolerance
- Read performance ok
- Write performance suffers

#### Fragmentation

- Multiple machines to distribute data
- Write performance ok
- Read performance suffers

# Wrap-Up (2)

- Fragmentation: need to coordinate operations across fragments
- Replication: need to synch to prevent inconsistent version
- Achieving ACID is challenging  $\rightarrow$  use CAP in distributed DB

# ACID work in a centralized database system, not in a distributed database system

[Ref: images from Pattamsetti, "Distributed Computing in Java 9"]

© Praphamontripong

# Wrap-Up (3)

- RDBMS intended to be highly consistent (boost availability by sacrificing some consistency)
- NoSQL intended to be highly available (boost consistency by sacrificing some availability)
- Relational database systems ACID
- Distributed database systems CAP
- NoSQL systems BASE
- Most applications compromise, depending business logic
  - Consistency / availability
  - Scalability
  - Usability
  - Analysis requirements

No silver-bullet !!
