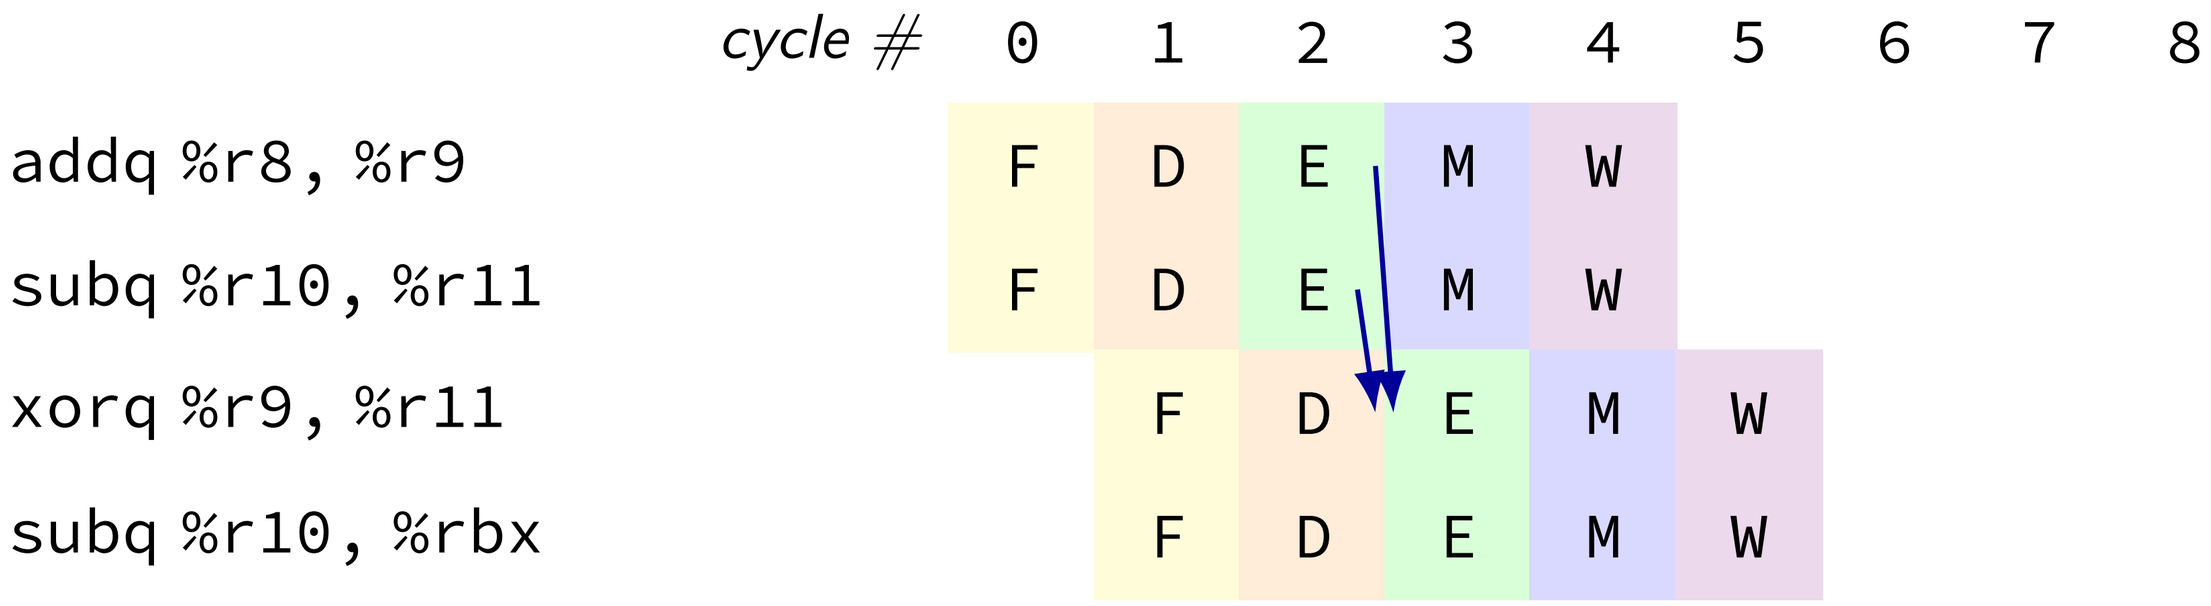
OOO

beyond pipelining: multiple issue

start *more than one instruction/cycle*

multiple parallel pipelines; many-input/output register file

hazard handling much more complex



beyond pipelining: out-of-order

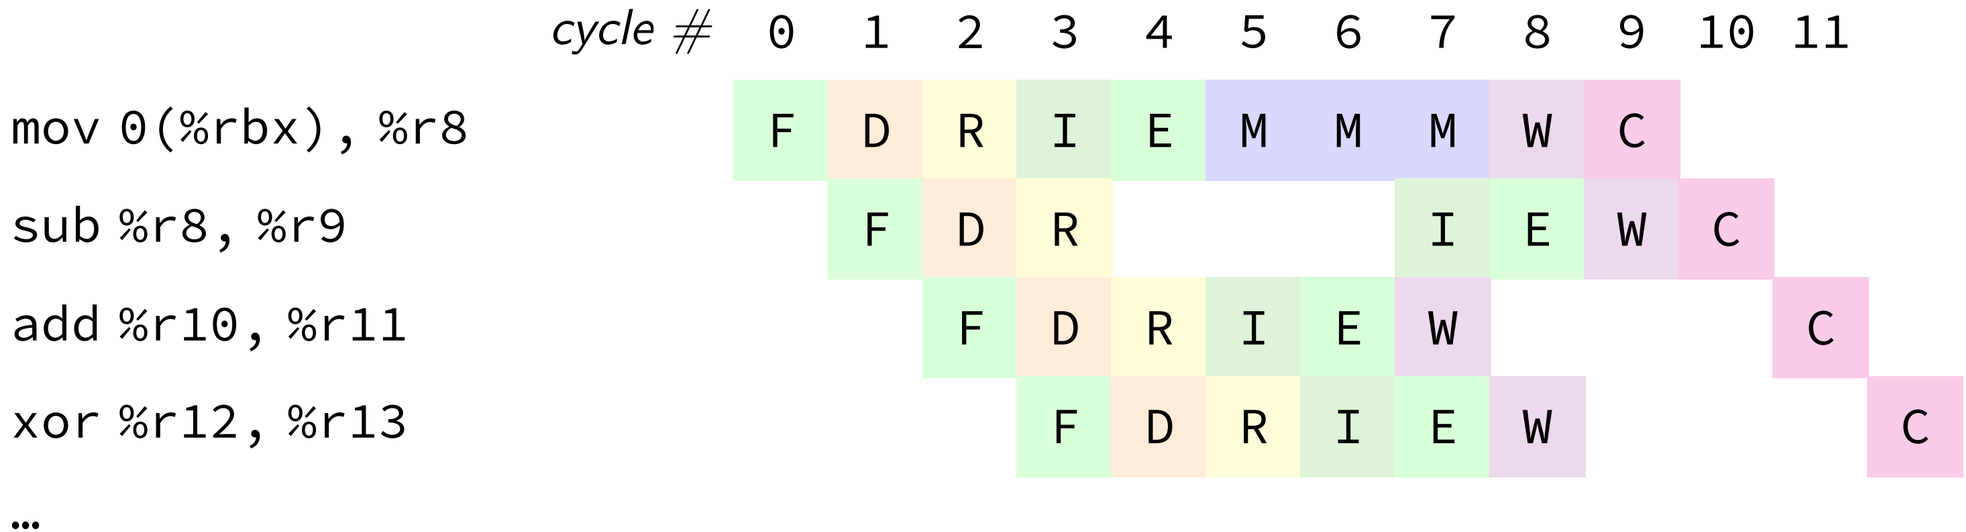
find *later instructions to do* instead of stalling

lists of available instructions in pipeline registers

- take any instruction with available values

provide *illusion that work is still done in order*

- much more complicated hazard handling logic



interlude: real CPUs

modern CPUs:

execute *multiple instructions at once*

execute instructions *out of order* — whenever *values available*

out-of-order and hazards

out-of-order execution makes hazards harder to handle

problems for forwarding:

- value in last stage may not be most up-to-date
- older value may be written back before newer value?

problems for branch prediction:

- mispredicted instructions may complete execution before squashing

which instructions to dispatch?

- how to quickly find instructions that are ready?

out-of-order and hazards

out-of-order execution makes hazards harder to handle

problems for forwarding:

- *value in last stage may not be most up-to-date*
- older value may be written back before newer value?

problems for branch prediction:

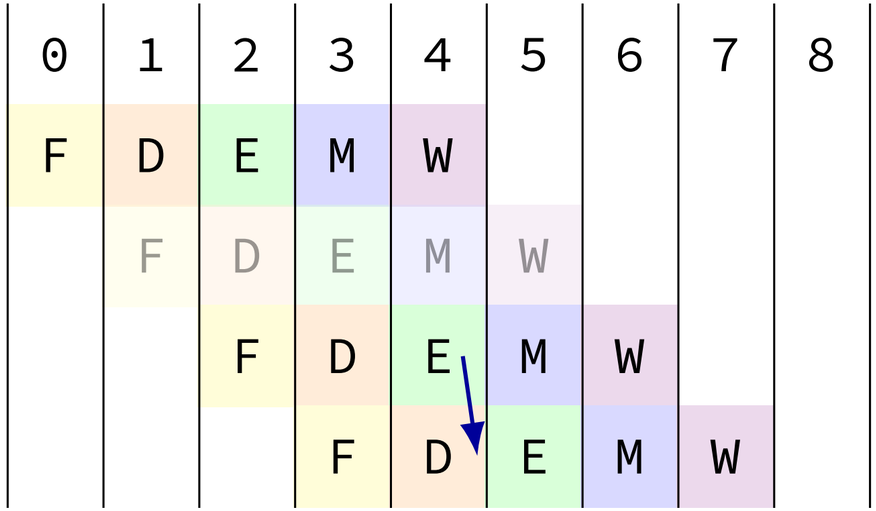
- mispredicted instructions may complete execution before squashing

which instructions to dispatch?

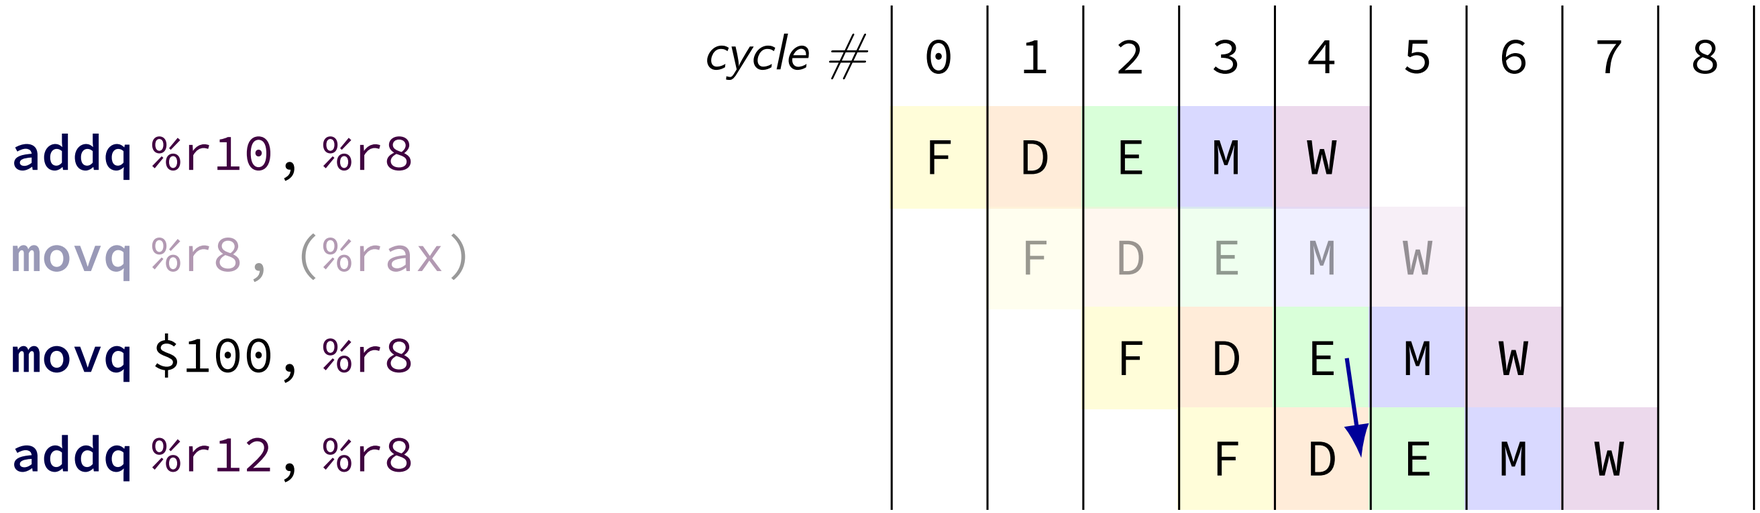
- how to quickly find instructions that are ready?

read-after-write examples (1)

```
addq %r10, %r8
movq %r8, (%rax)
movq $100, %r8
addq %r12, %r8
```

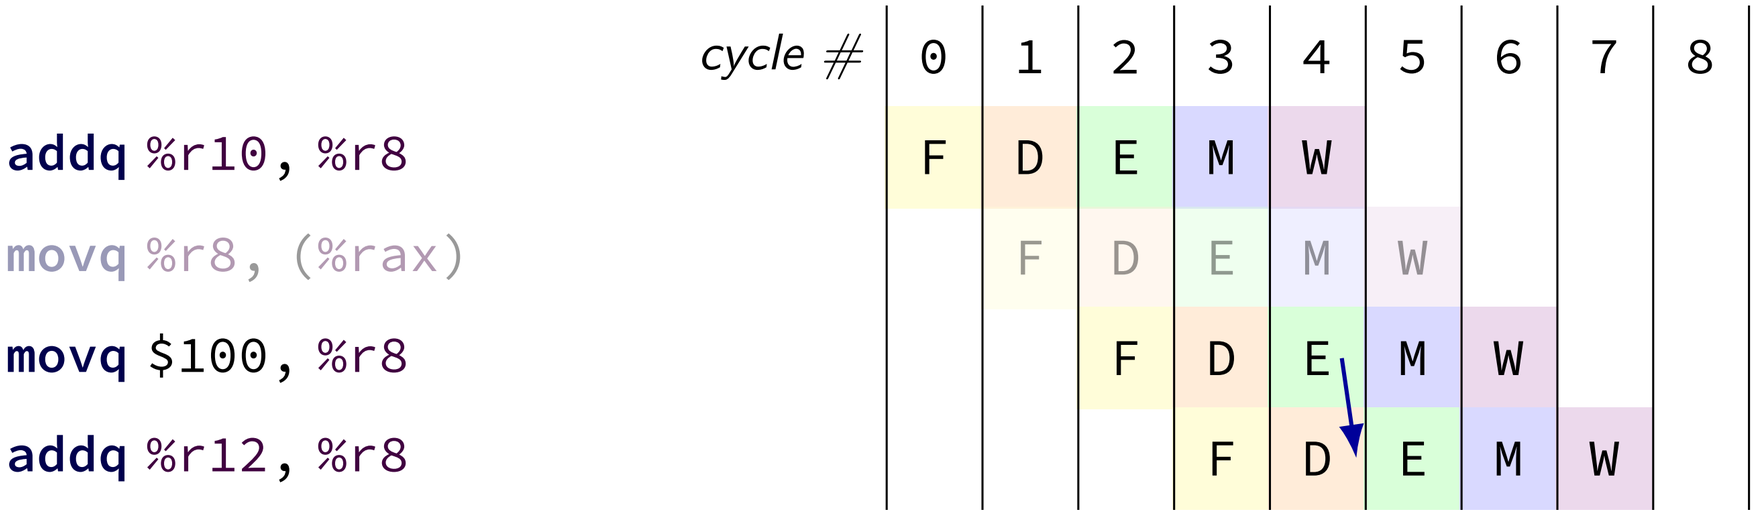


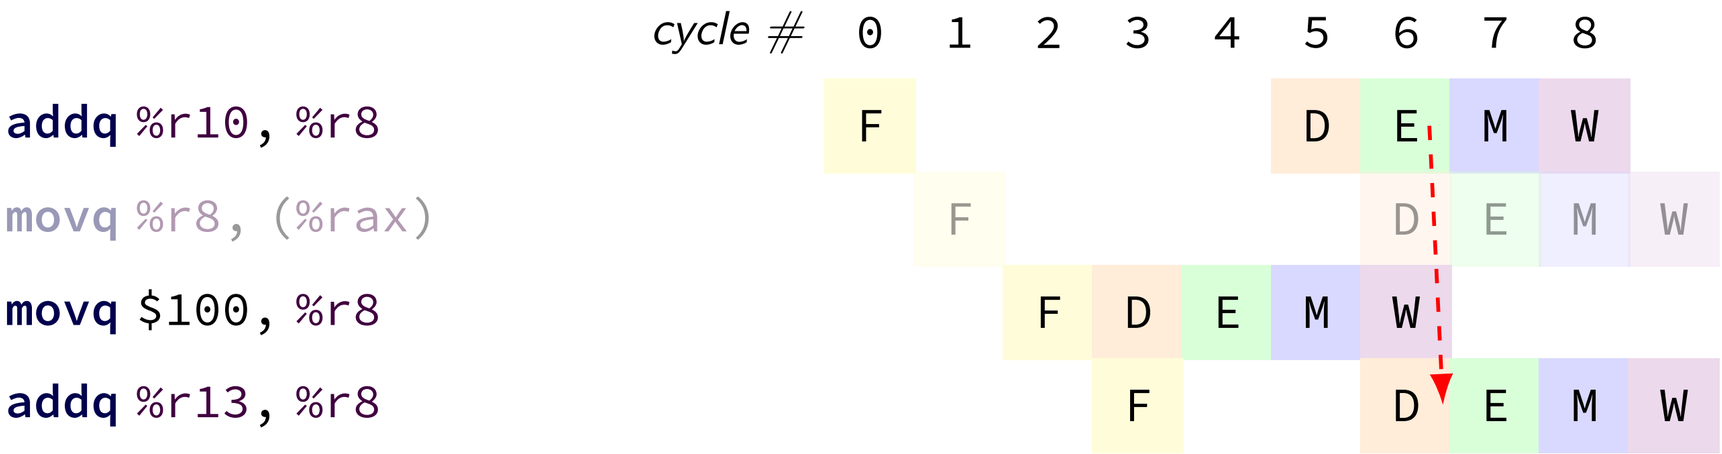
read-after-write examples (1)



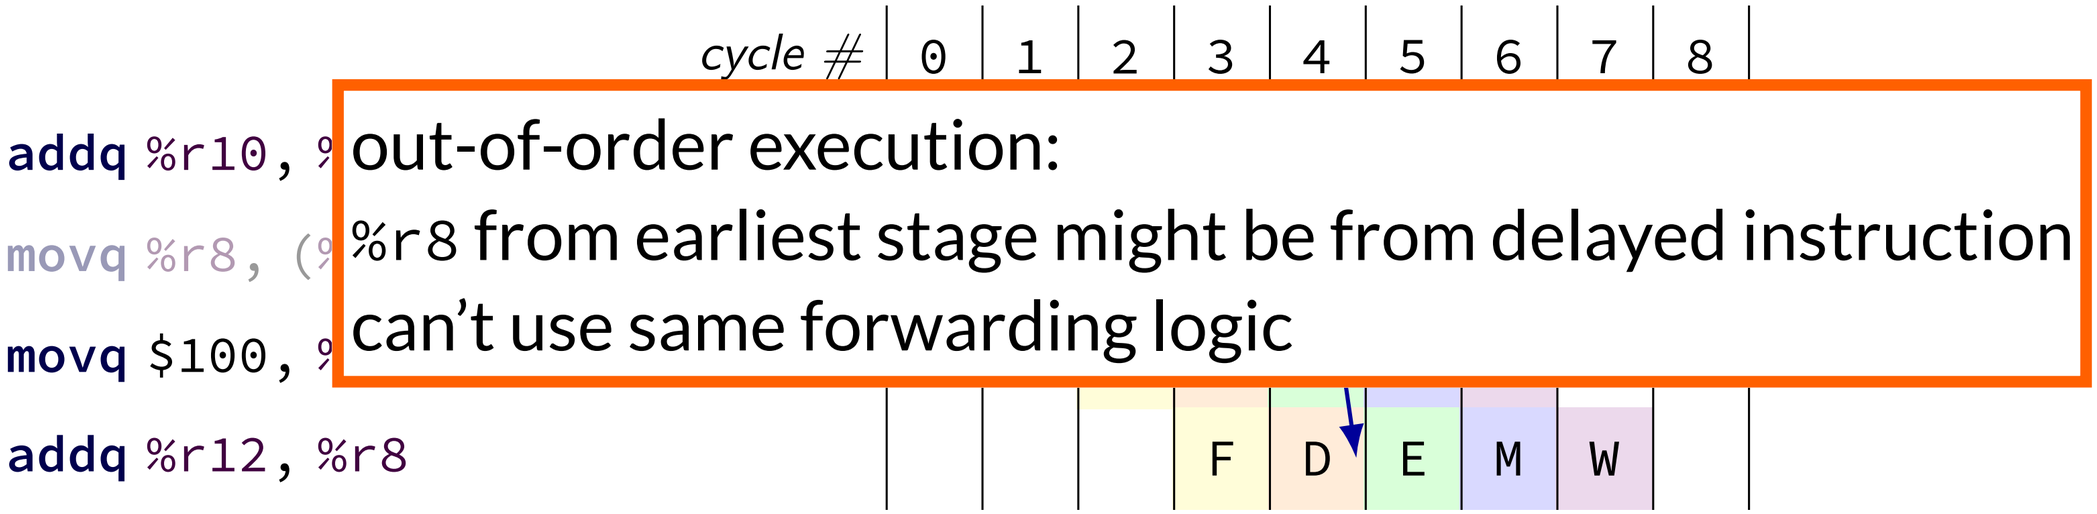
normal pipeline: two options for %r8?
choose the one from *earliest stage*
because it's from the most recent instruction

read-after-write examples (1)





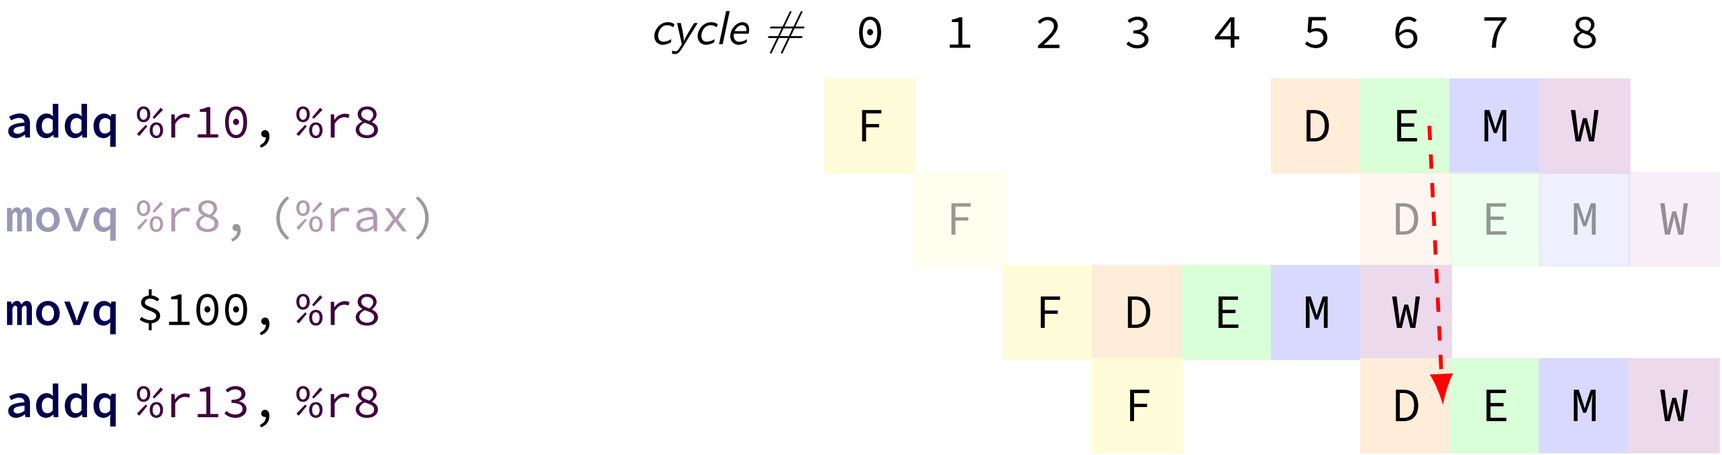
read-after-write examples (1)



out-of-order execution:

`%r8` from earliest stage might be from delayed instruction

can't use same forwarding logic



register version tracking

goal: track *different versions of registers*

out-of-order execution: may compute versions at different times

only forward the *correct version*

strategy for doing this: preprocess instructions represent version info

makes forwarding, etc. lookup easier

rewriting hazard examples (1)

addq %r10, %r8	addq $\%r10_{v1}, \%r8_{v1} \rightarrow \%r8_{v2}$
addq %r11, %r8	addq $\%r11_{v1}, \%r8_{v2} \rightarrow \%r8_{v3}$
addq %r12, %r8	addq $\%r12_{v1}, \%r8_{v3} \rightarrow \%r8_{v4}$

---

read different version than the one written

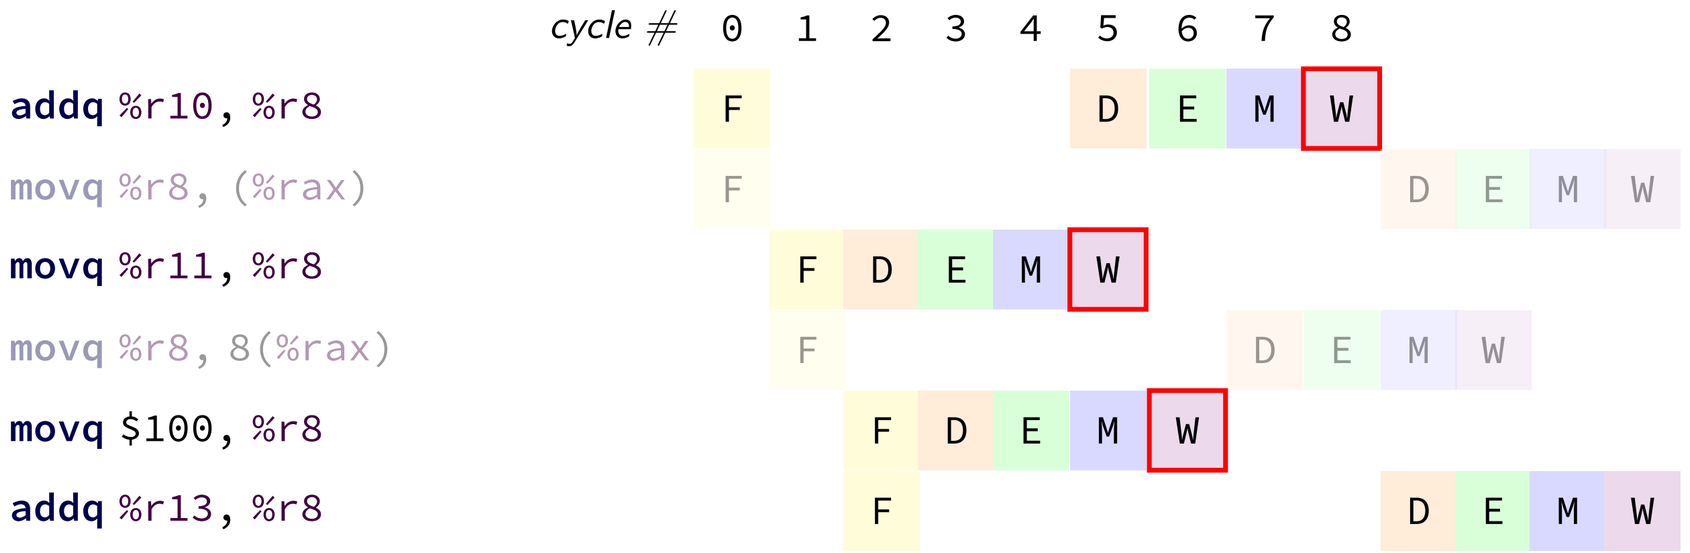
- represent with three argument psuedo-instructions

forwarding a value? must match version *exactly*

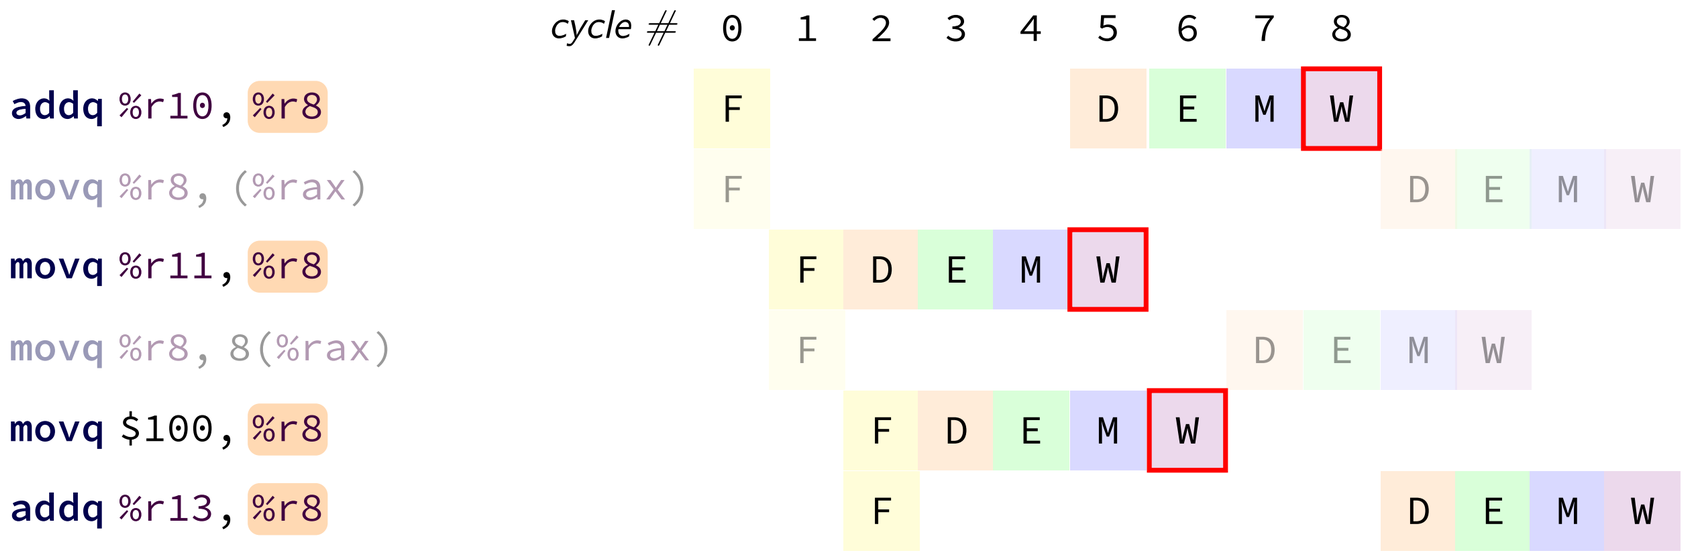
for now: version numbers

later: something simpler to implement

write-after-write example



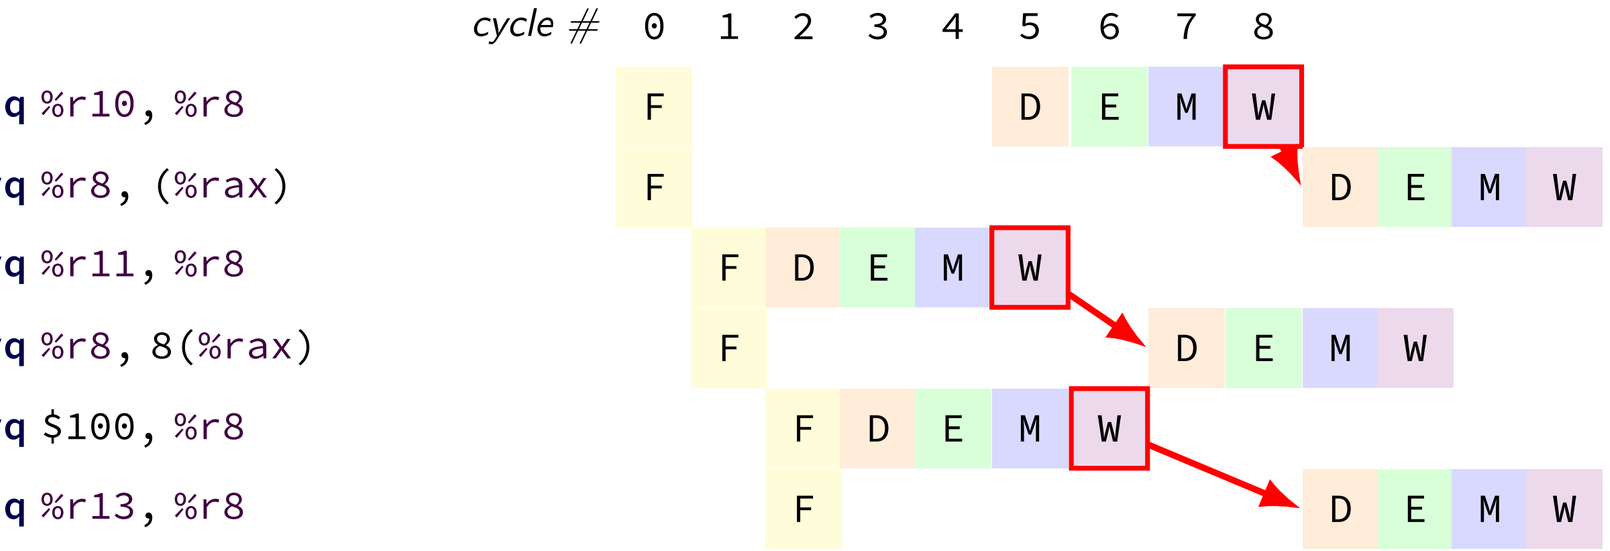
write-after-write example



many instructions producing differnt version of `%r8`
most recently run instruction may be writing *outdated version*

write-after-write example

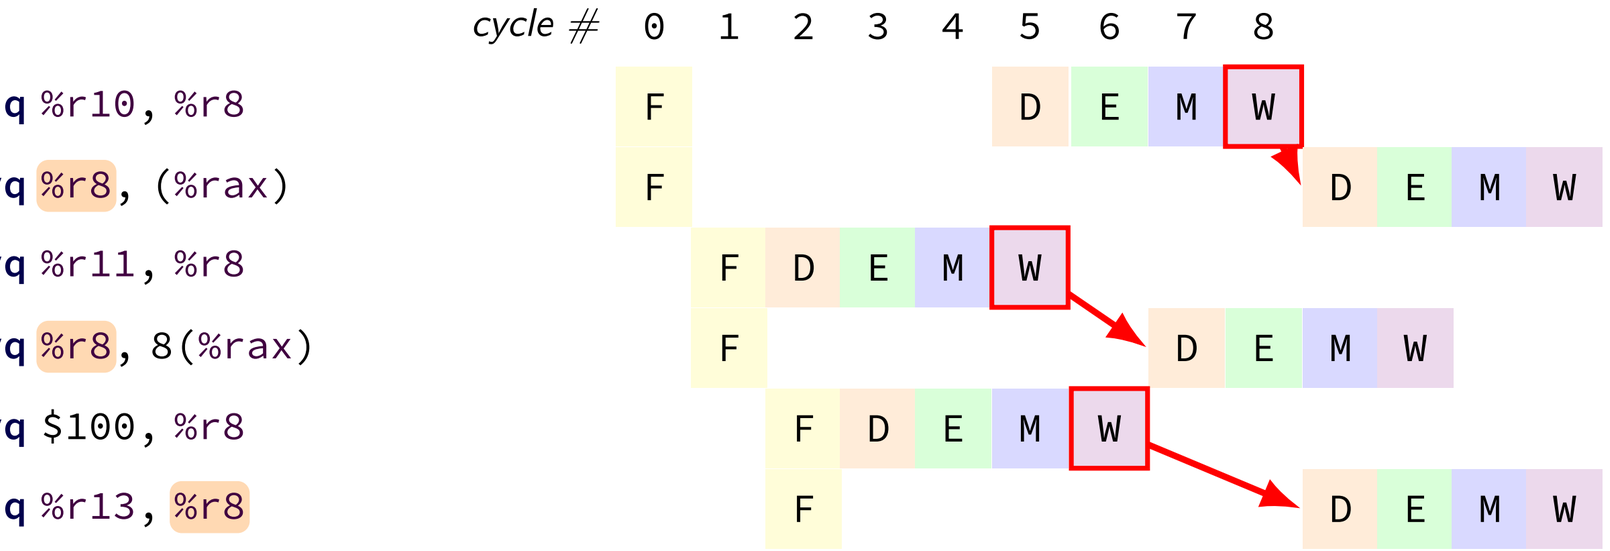
```
addq %r10, %r8
movq %r8, (%rax)
movq %r11, %r8
movq %r8, 8(%rax)
movq $100, %r8
addq %r13, %r8
```



multiple instructions that haven't started could need *different versions* of `%r8`

write-after-write example

```
addq %r10, %r8
movq %r8, (%rax)
movq %r11, %r8
movq %r8, 8(%rax)
movq $100, %r8
addq %r13, %r8
```



keeping multiple versions

for write-after-write problem: need to keep copies of multiple versions

both the new version and the old version needed by delayed instructions

for read-after-write problem: need to distinguish different versions

solution: *have lots of extra registers*

… and assign each version a new 'real' register

called *register renaming*

register renaming

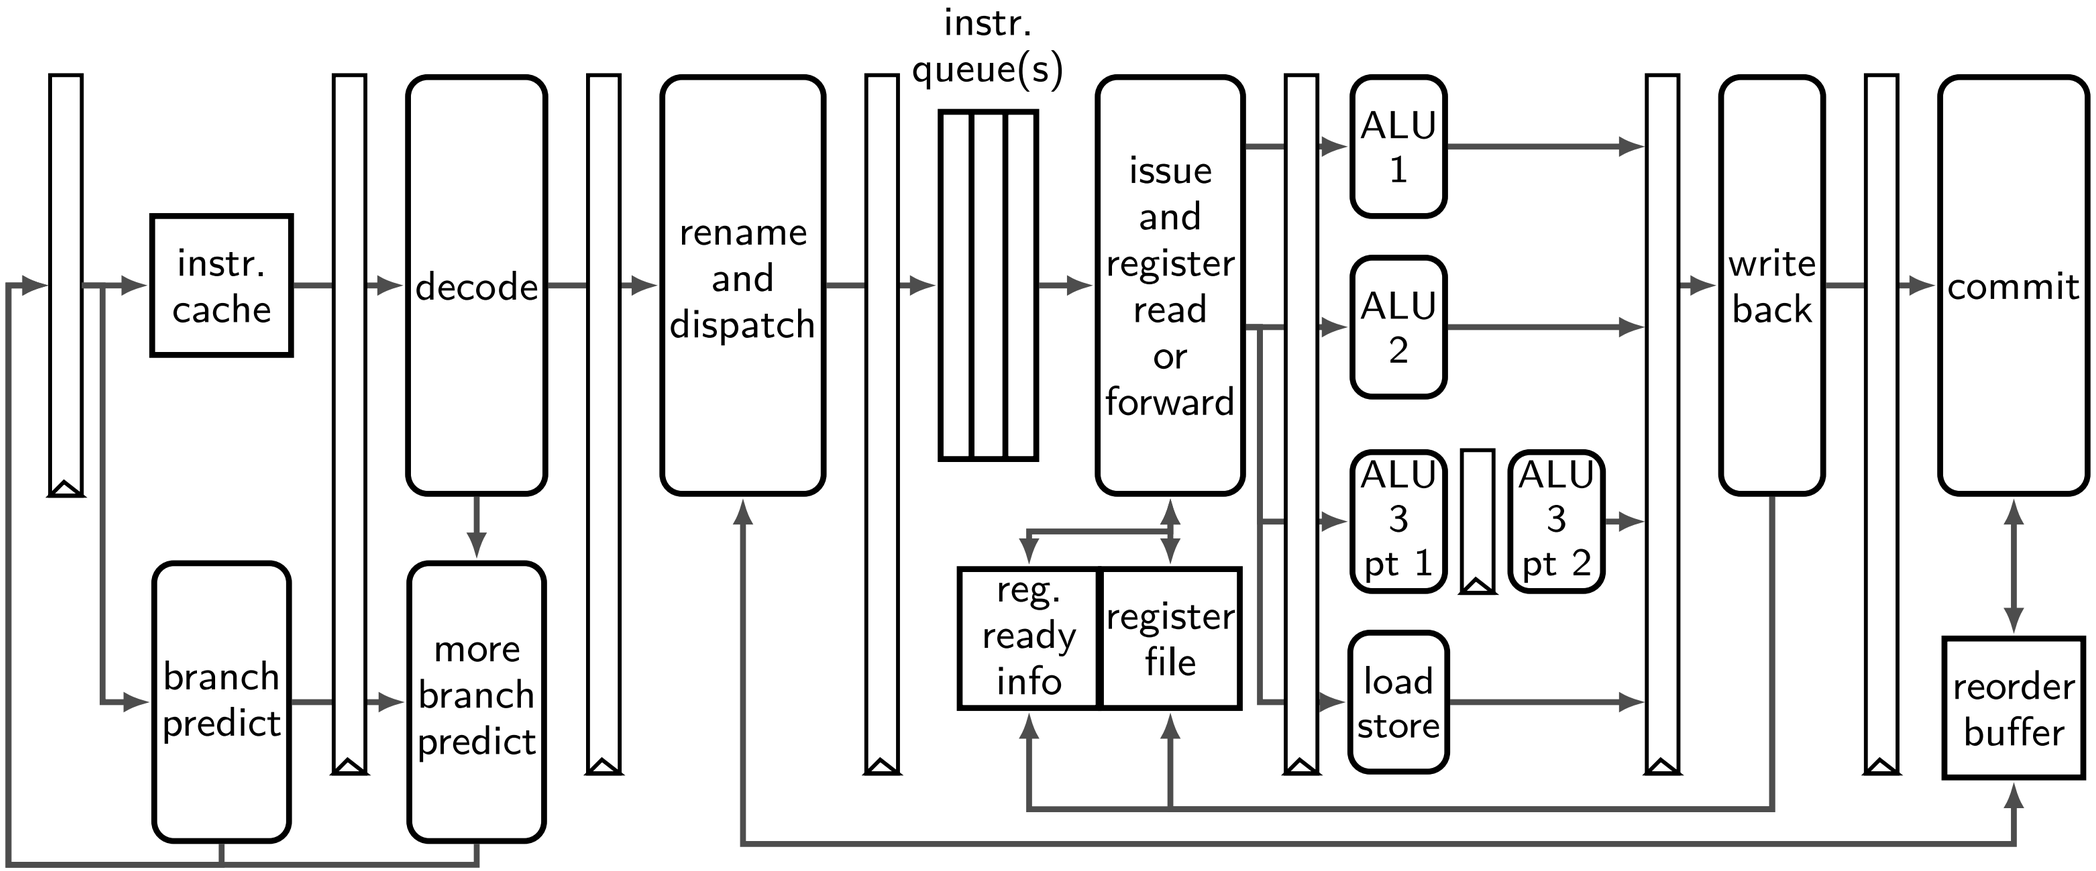
rename *architectural registers* to *physical registers*

different physical register for each version of architectural

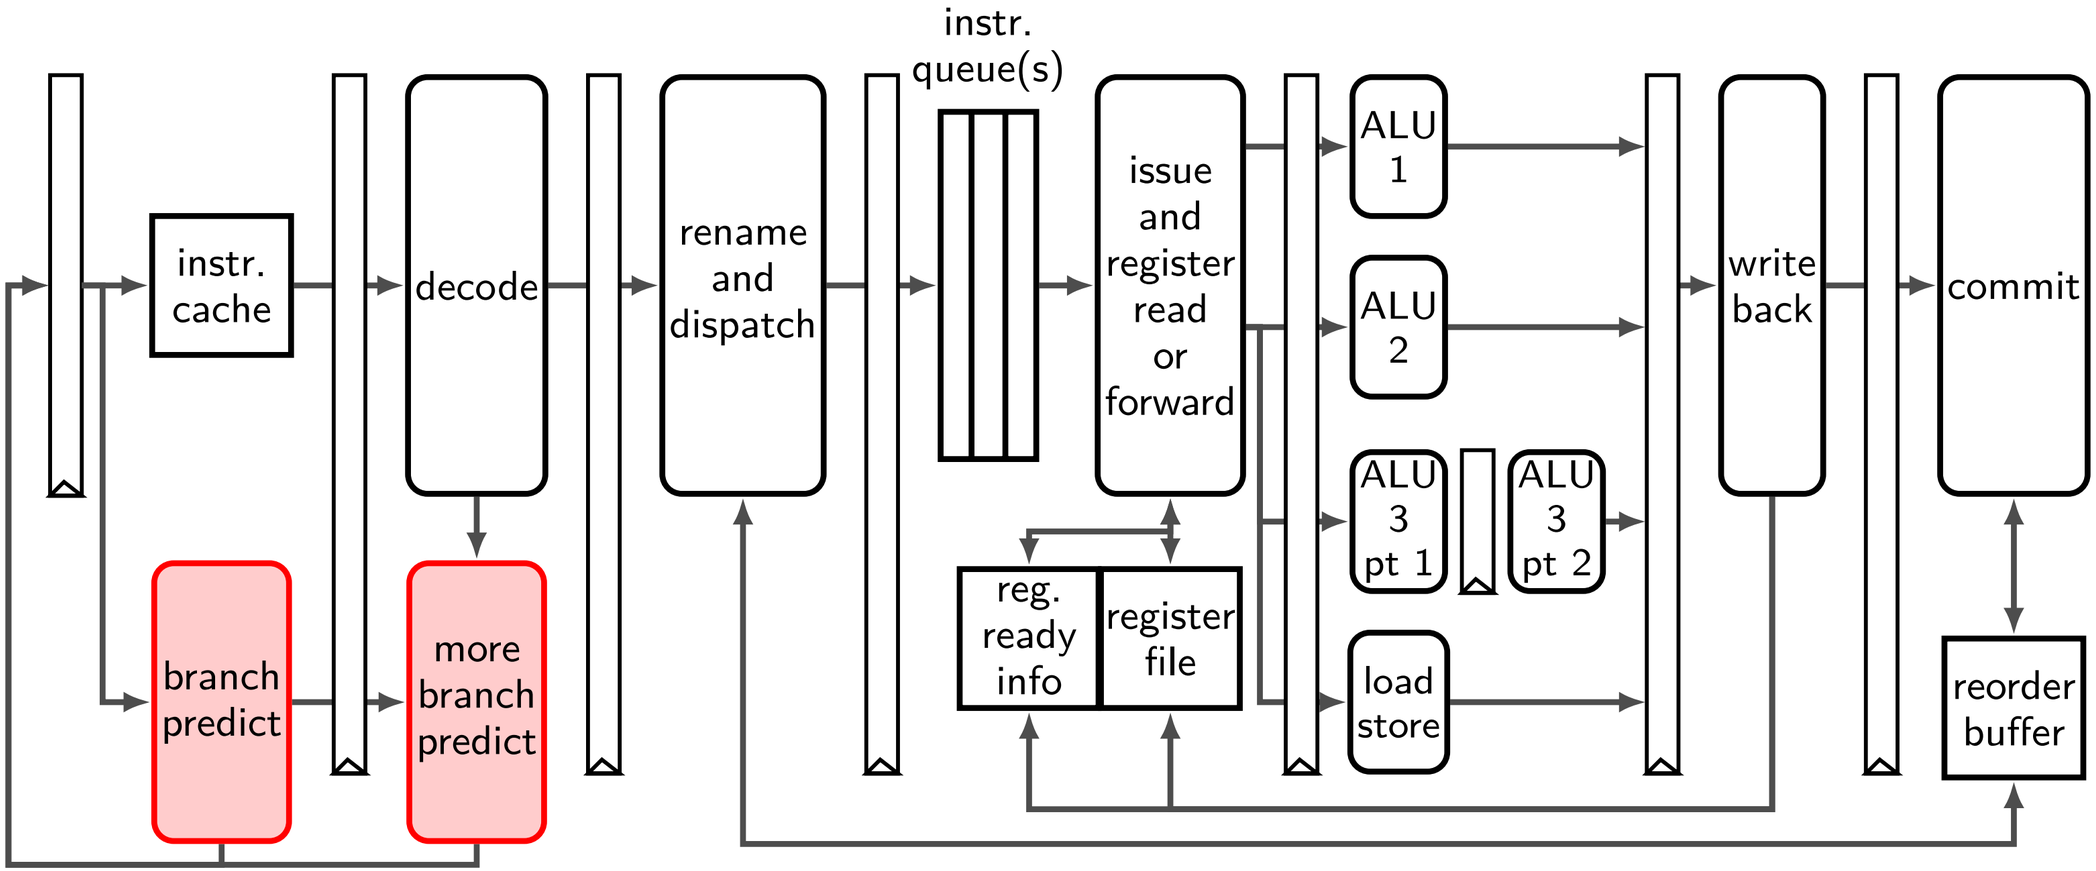
track which physical registers are ready

compare physical register numbers to do forwarding

an OOO pipeline

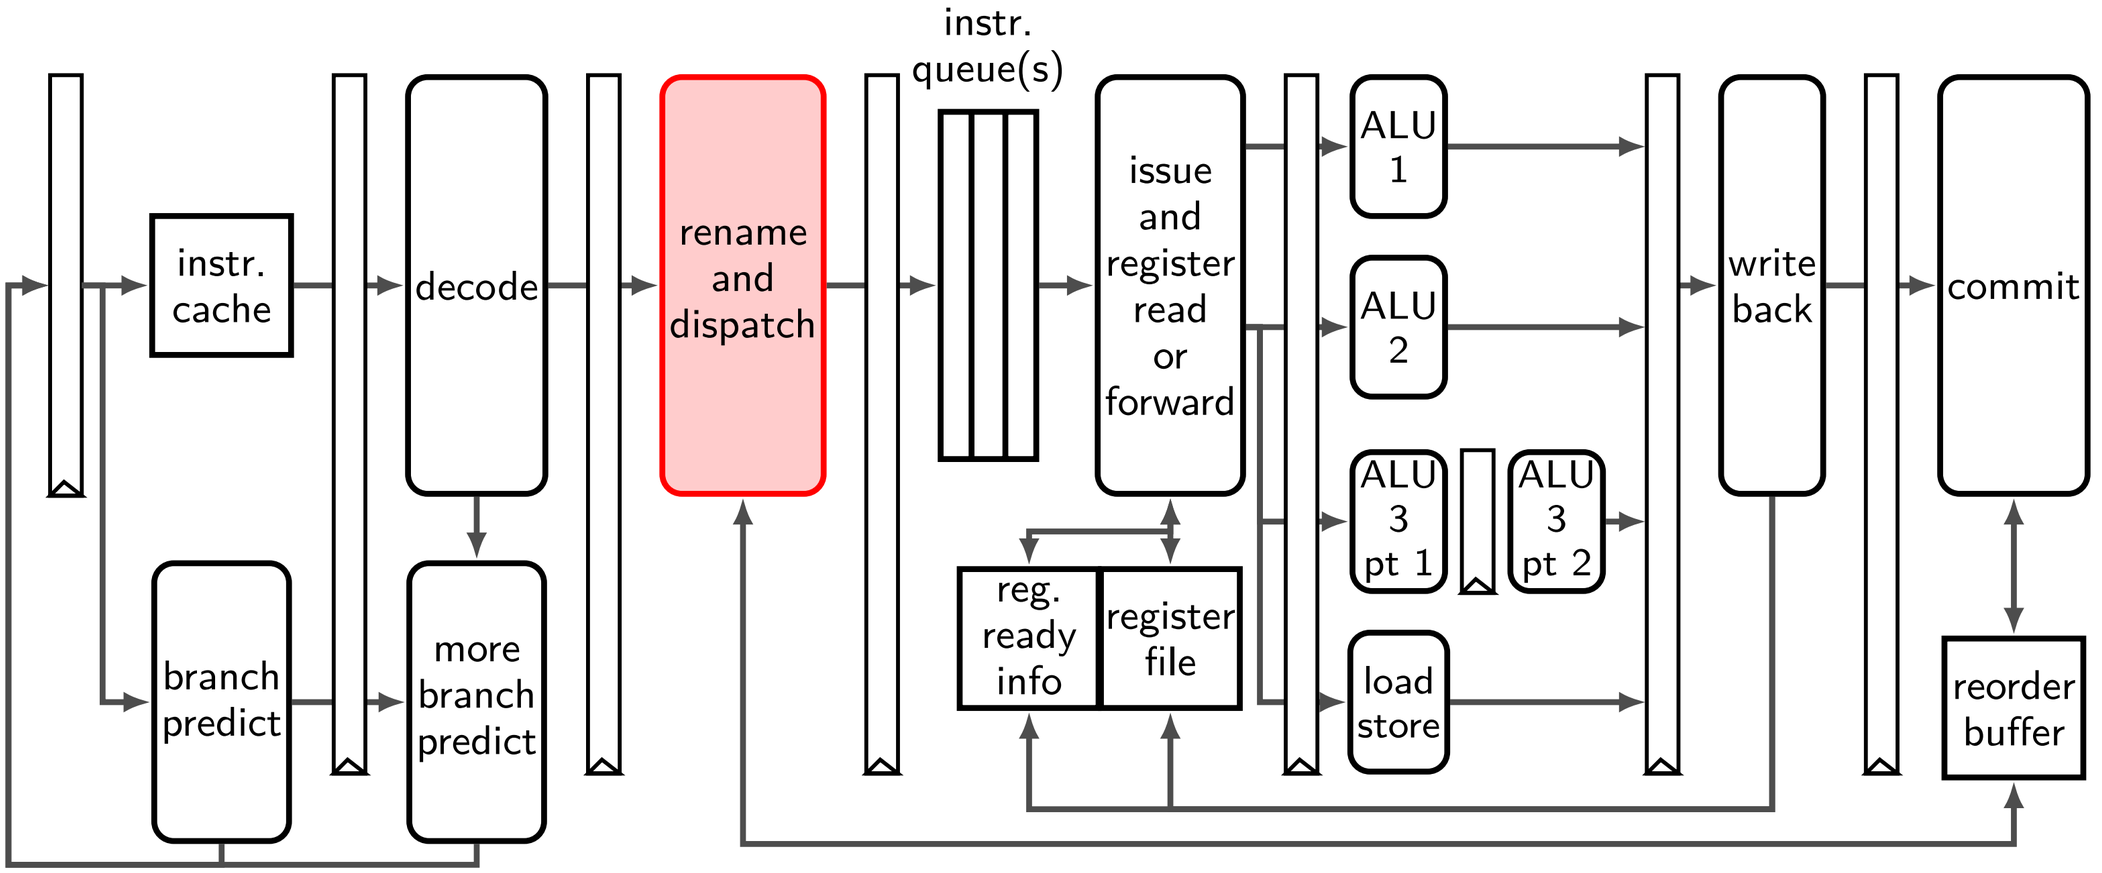


an OOO pipeline (branch prediction)



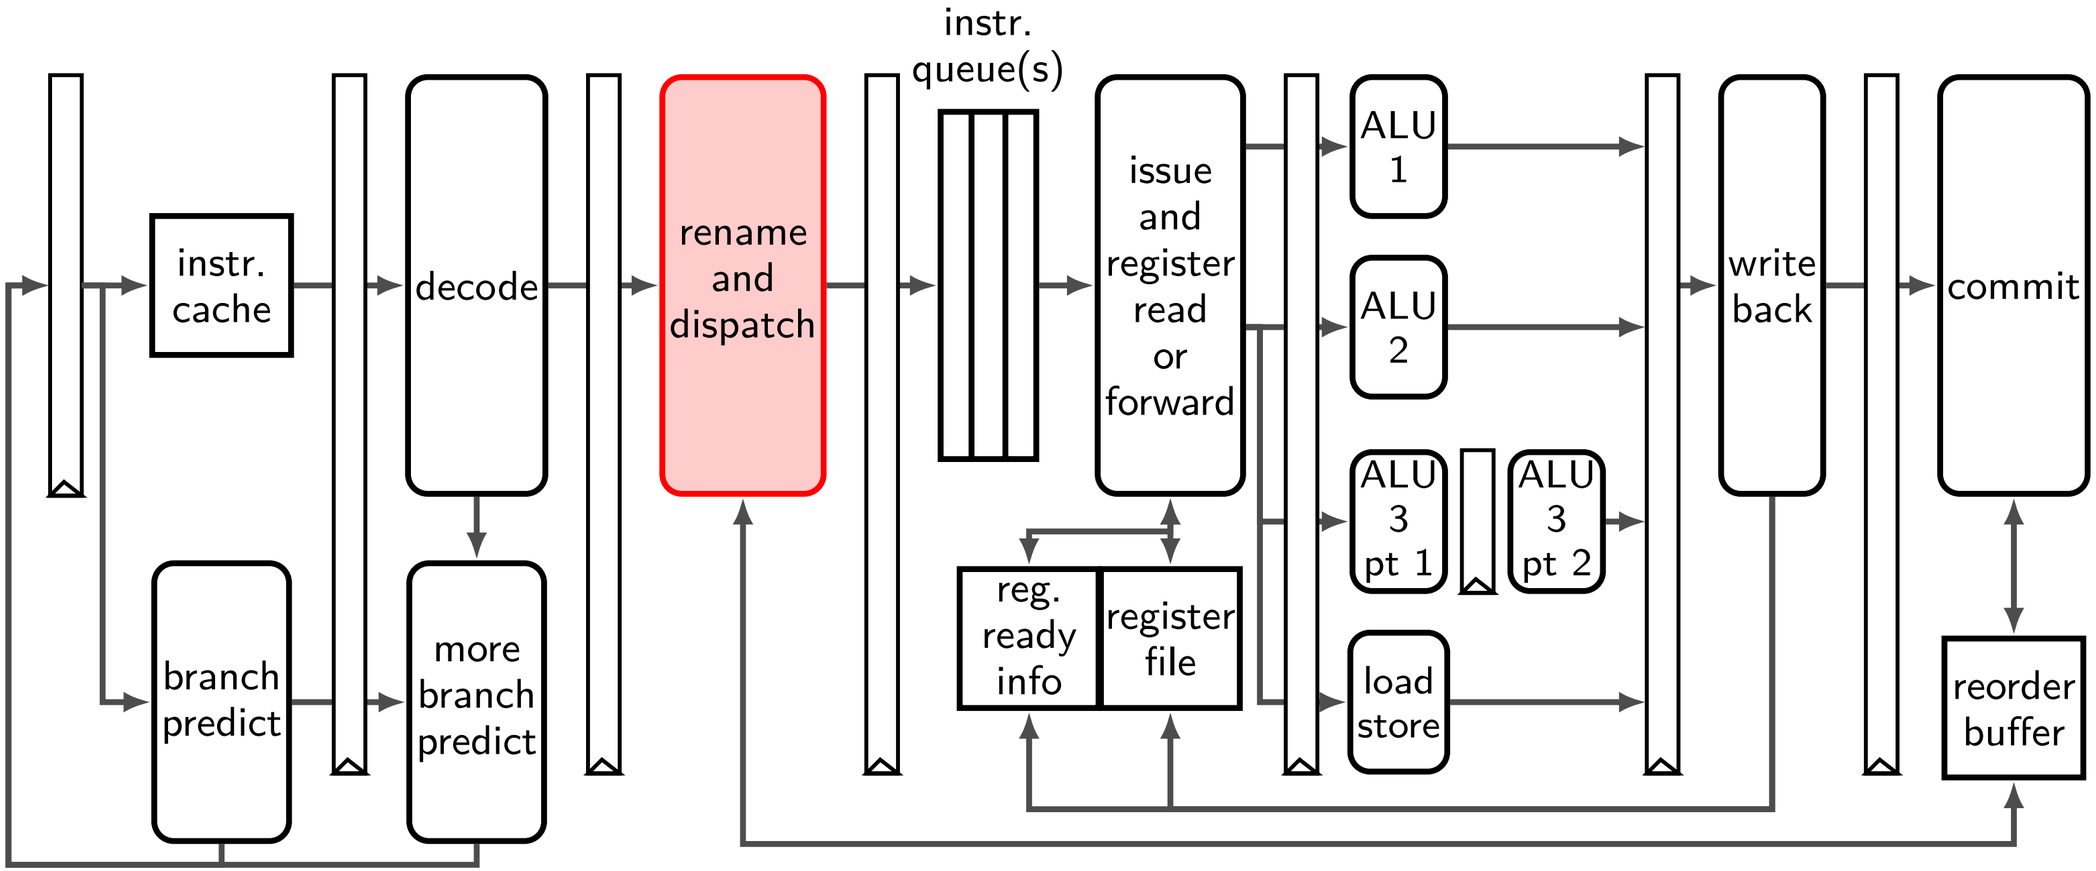
branch prediction needs to happen before instructions decoded
done with cache-like tables of information about recent branches

an OOO pipeline (register renaming)



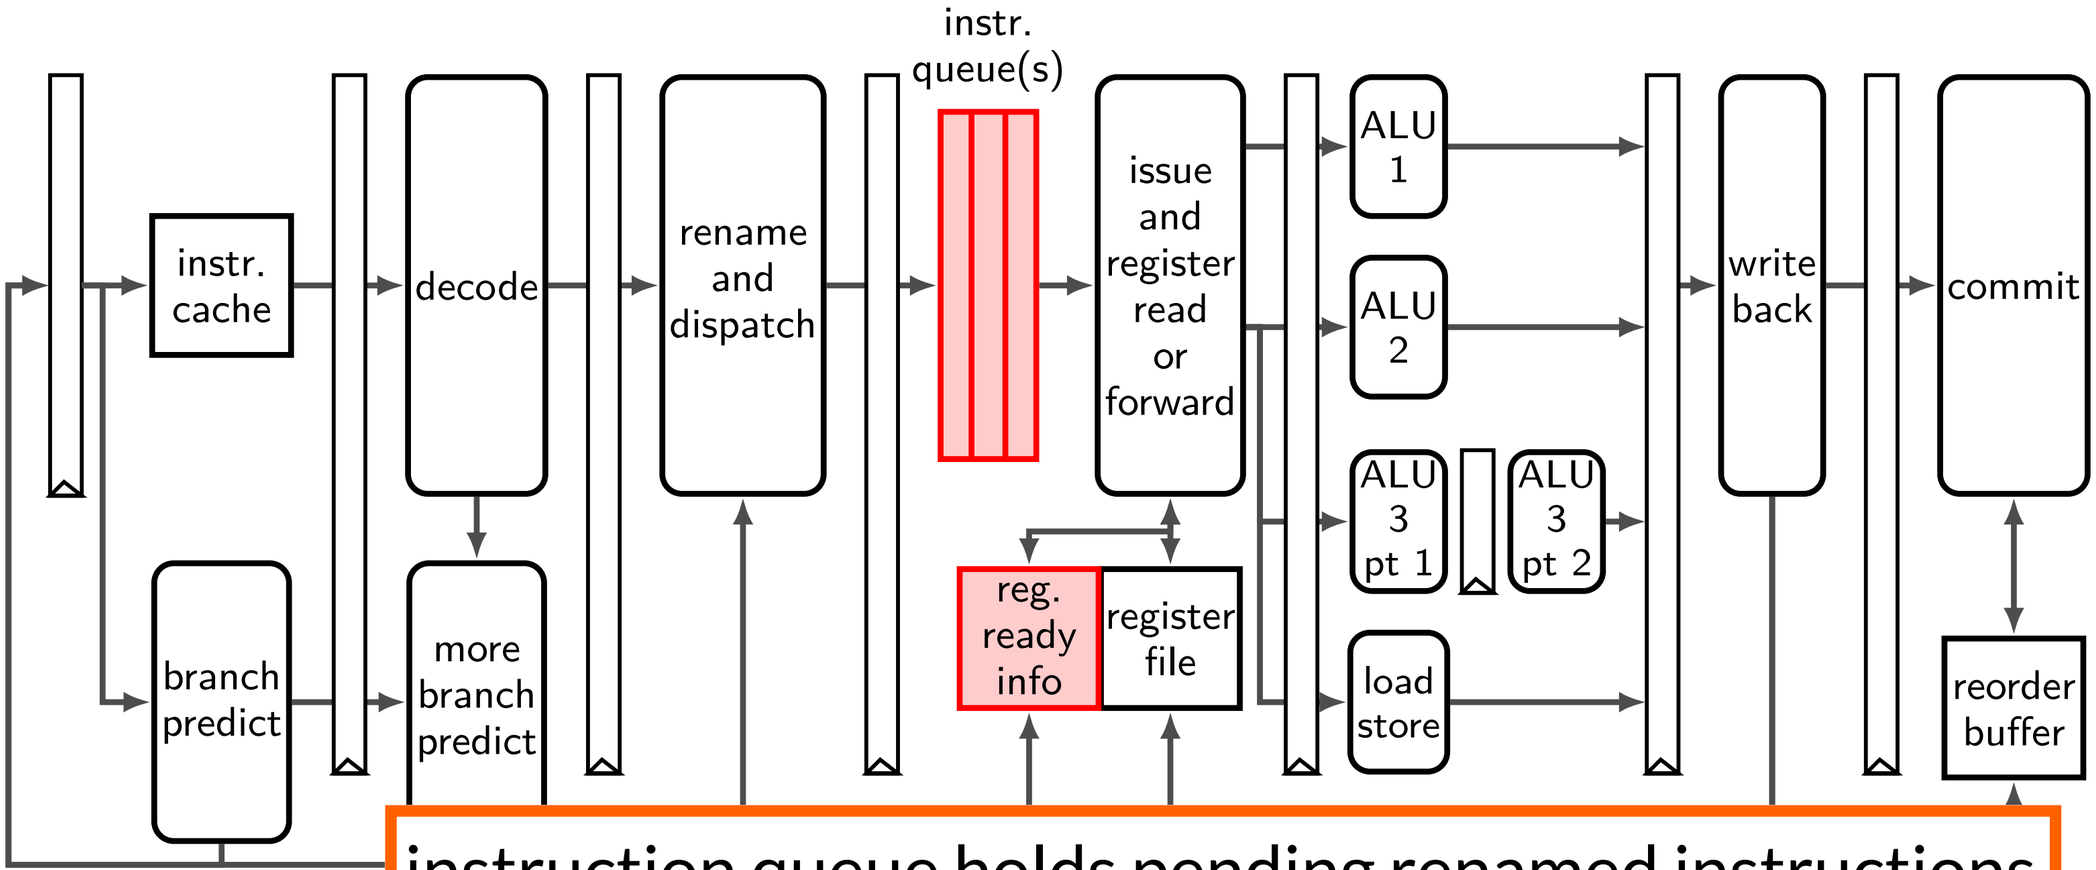
register renaming after decoding
where mapping from architectural to physical names kept

an OOO pipeline (register renaming)



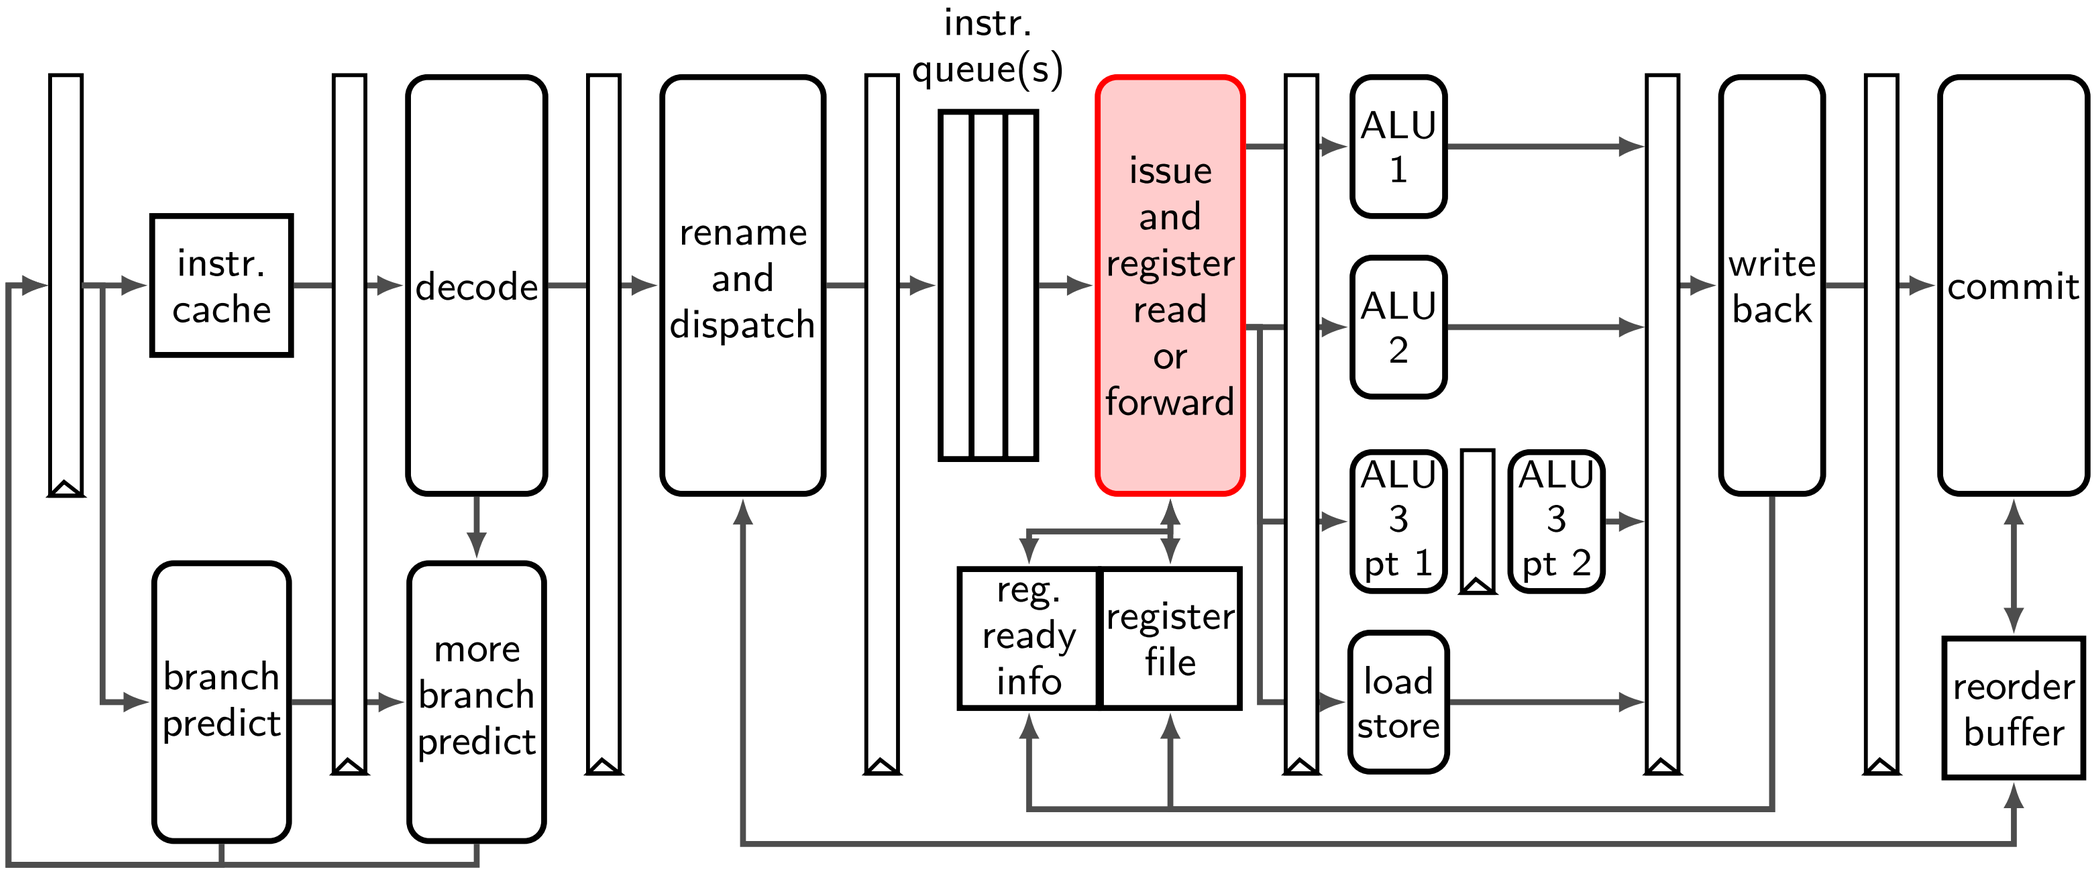
"dispatch" instructions = add to instruction queue
also requires preparing reorder buffer (for handling squashing)

an OOO pipeline (instruction queue)



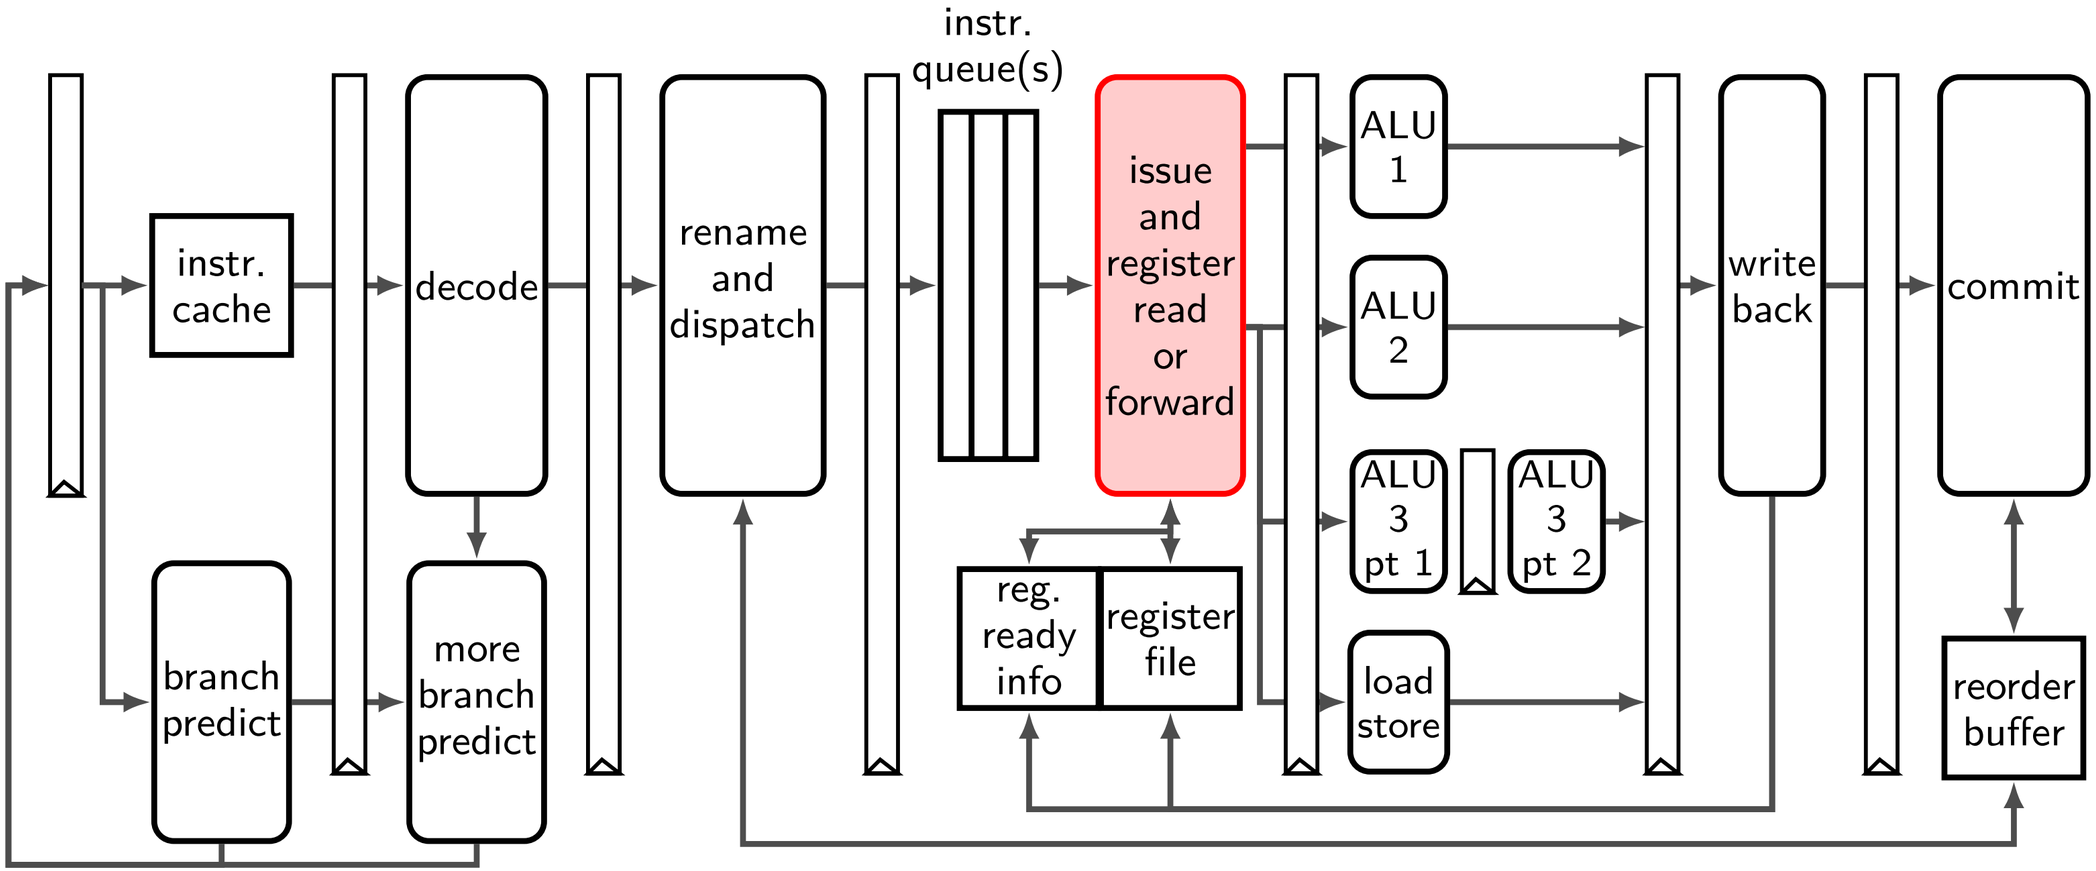
instruction queue holds pending renamed instructions combined with register-ready info to *issue* instructions (*issue* = start executing)

an OOO pipeline (starting instruction)



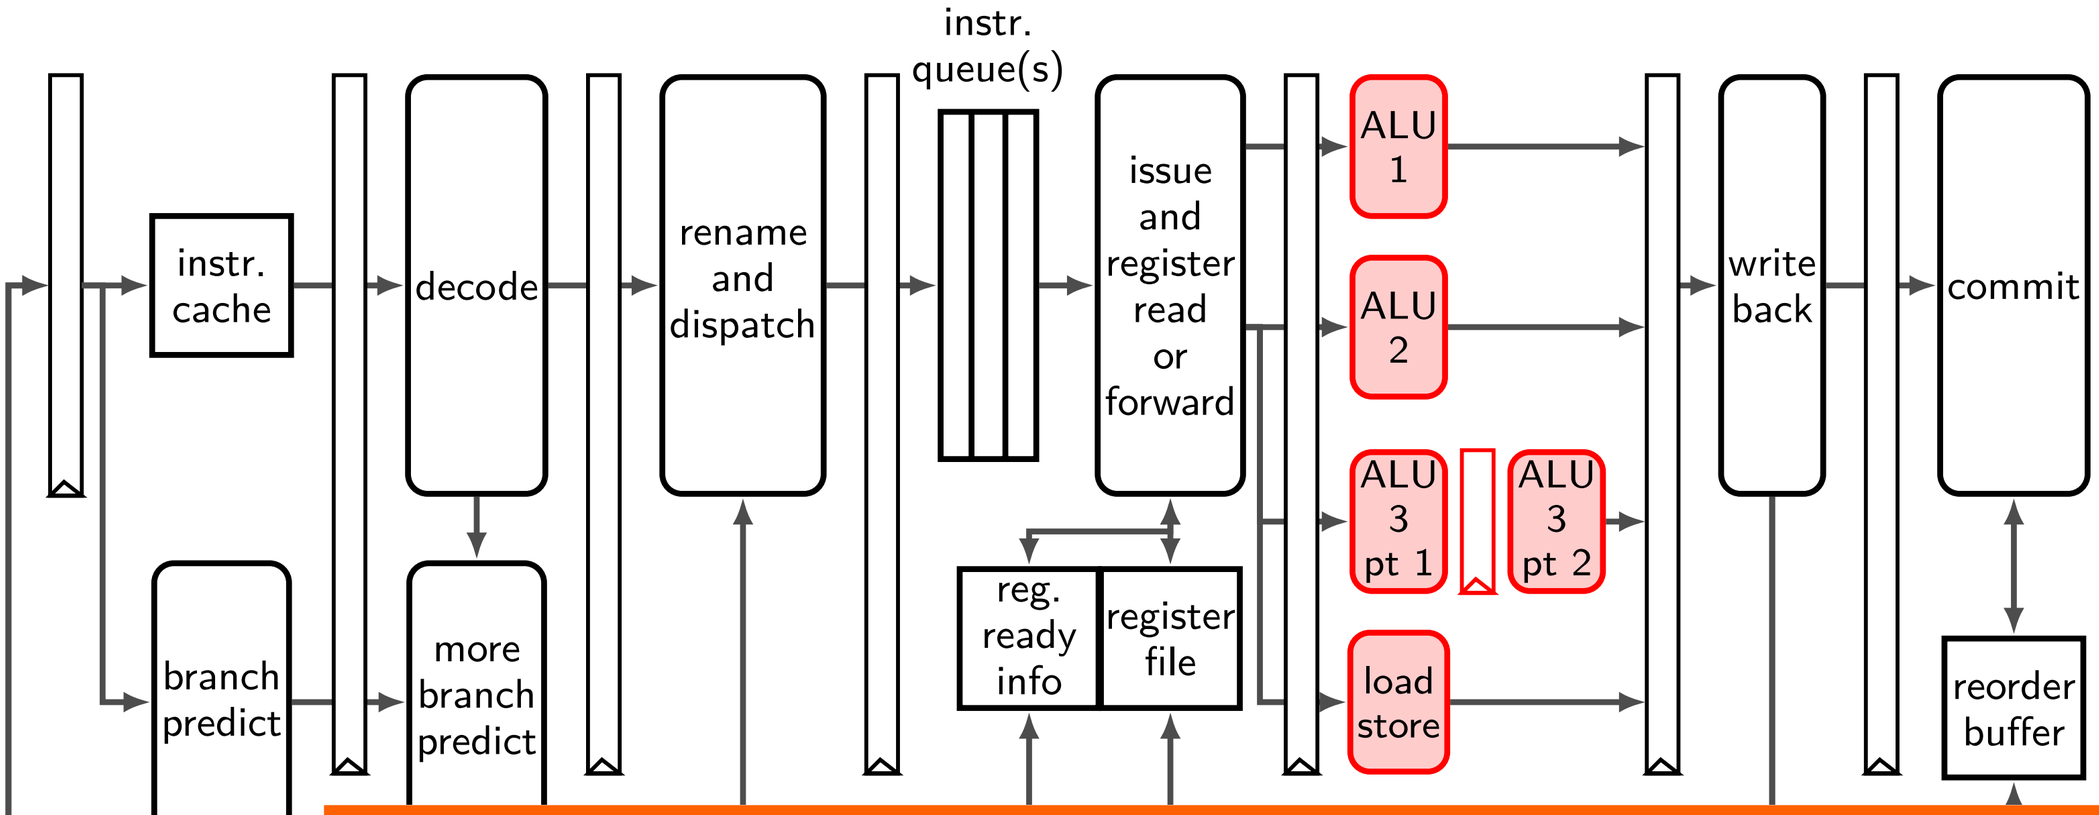
after selecting from instruction queue,
read from large register file and handle forwarding

an OOO pipeline (starting instruction)



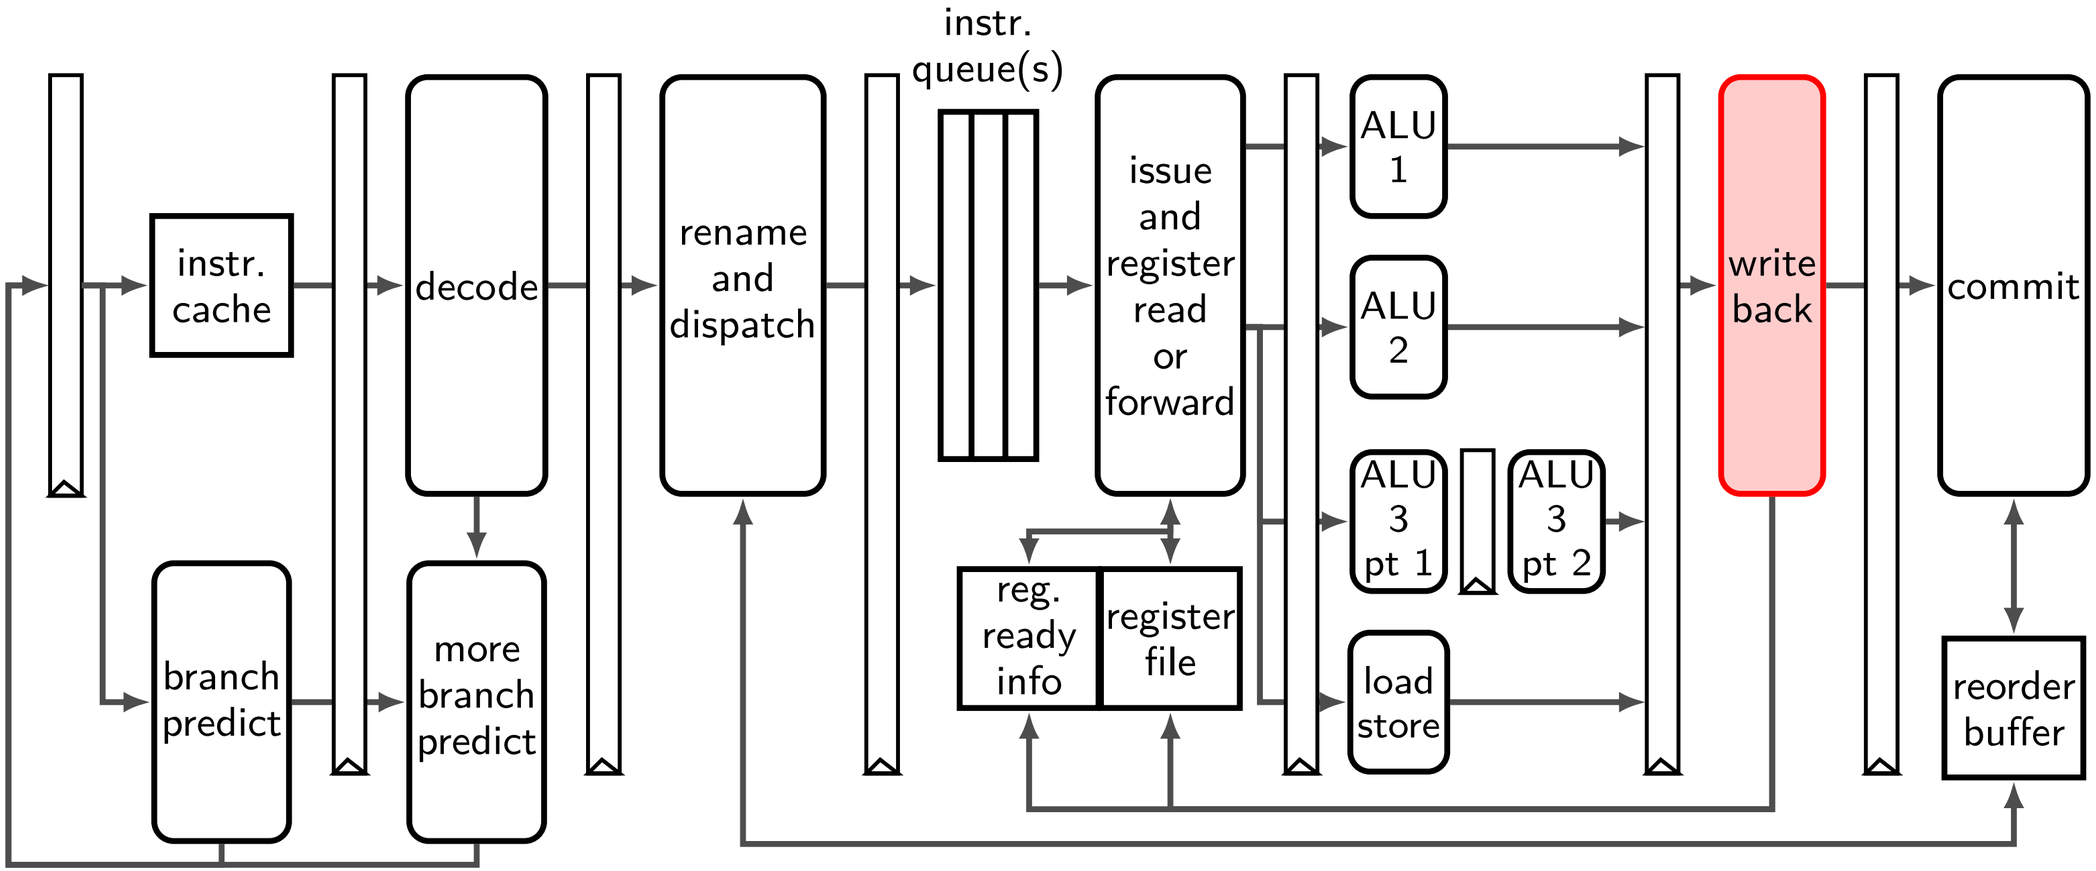
typically read 6+ registers at a time
extra data paths for forwarding (not drawn)

an OOO pipeline (execution units)



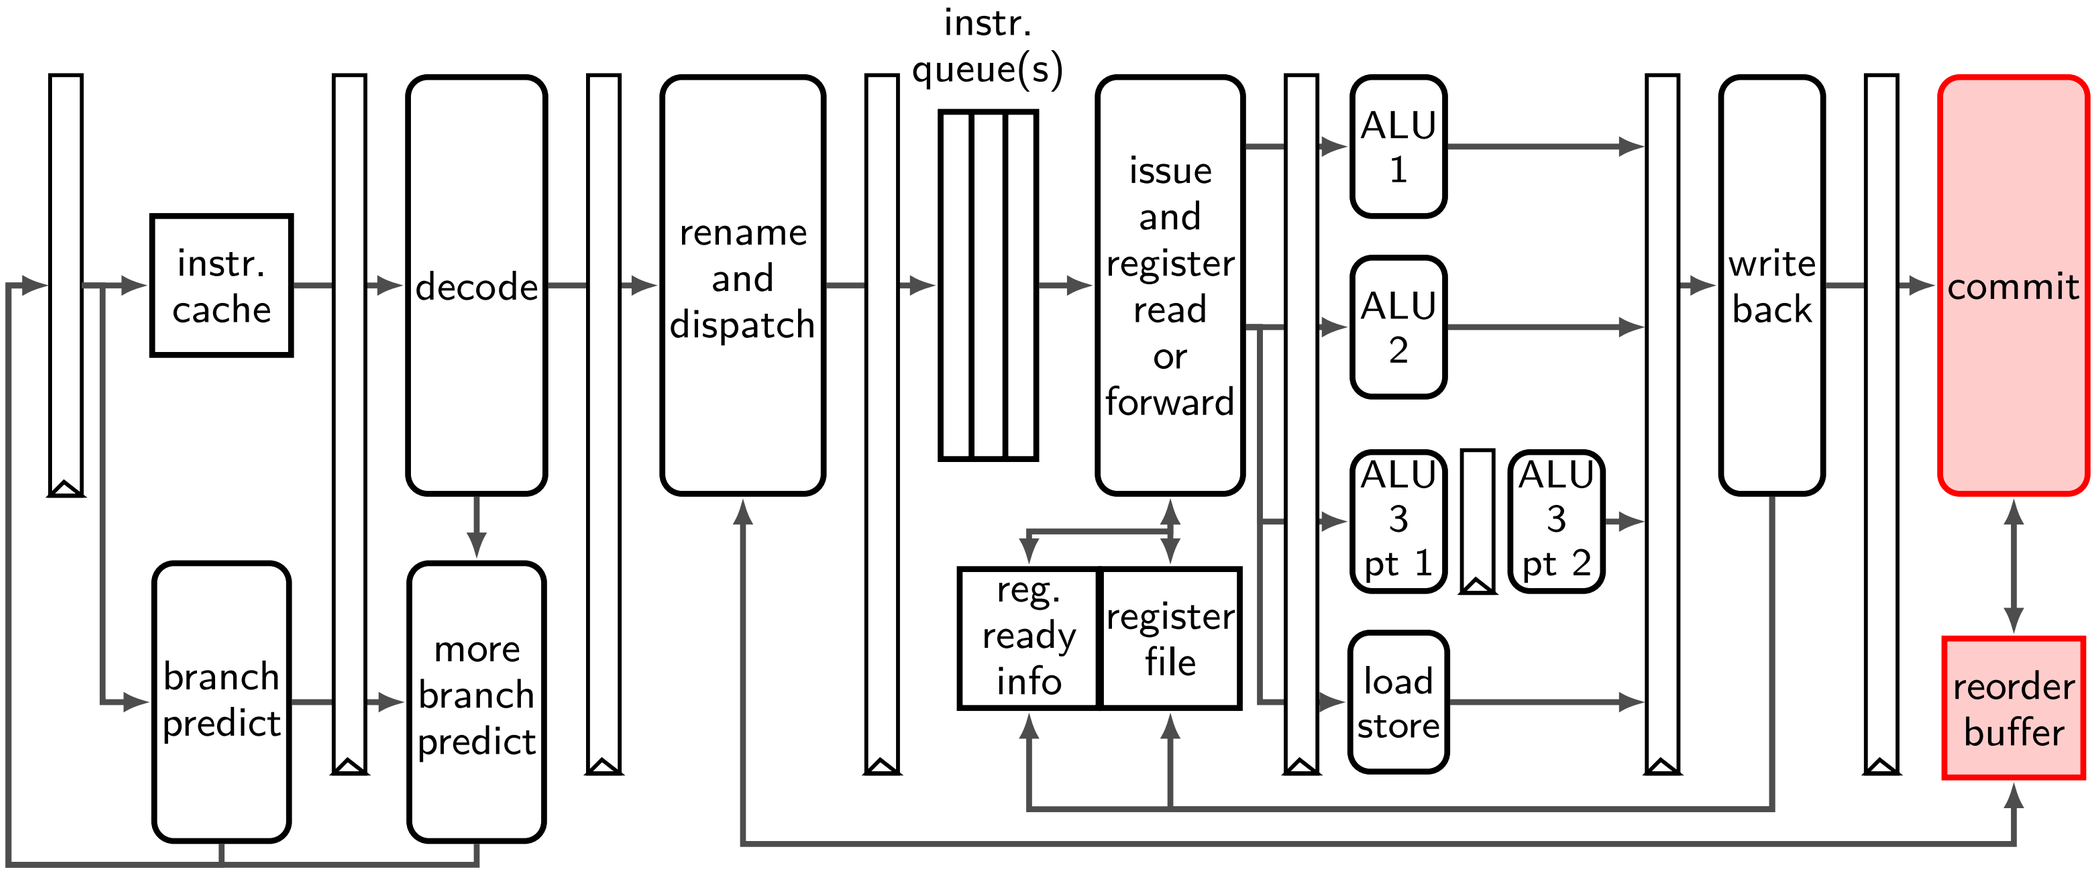
many *execution units* actually do math or cache load/store
some may have multiple pipeline stages
some may take variable time (data cache, integer divide, ...)

an OOO pipeline (writeback)



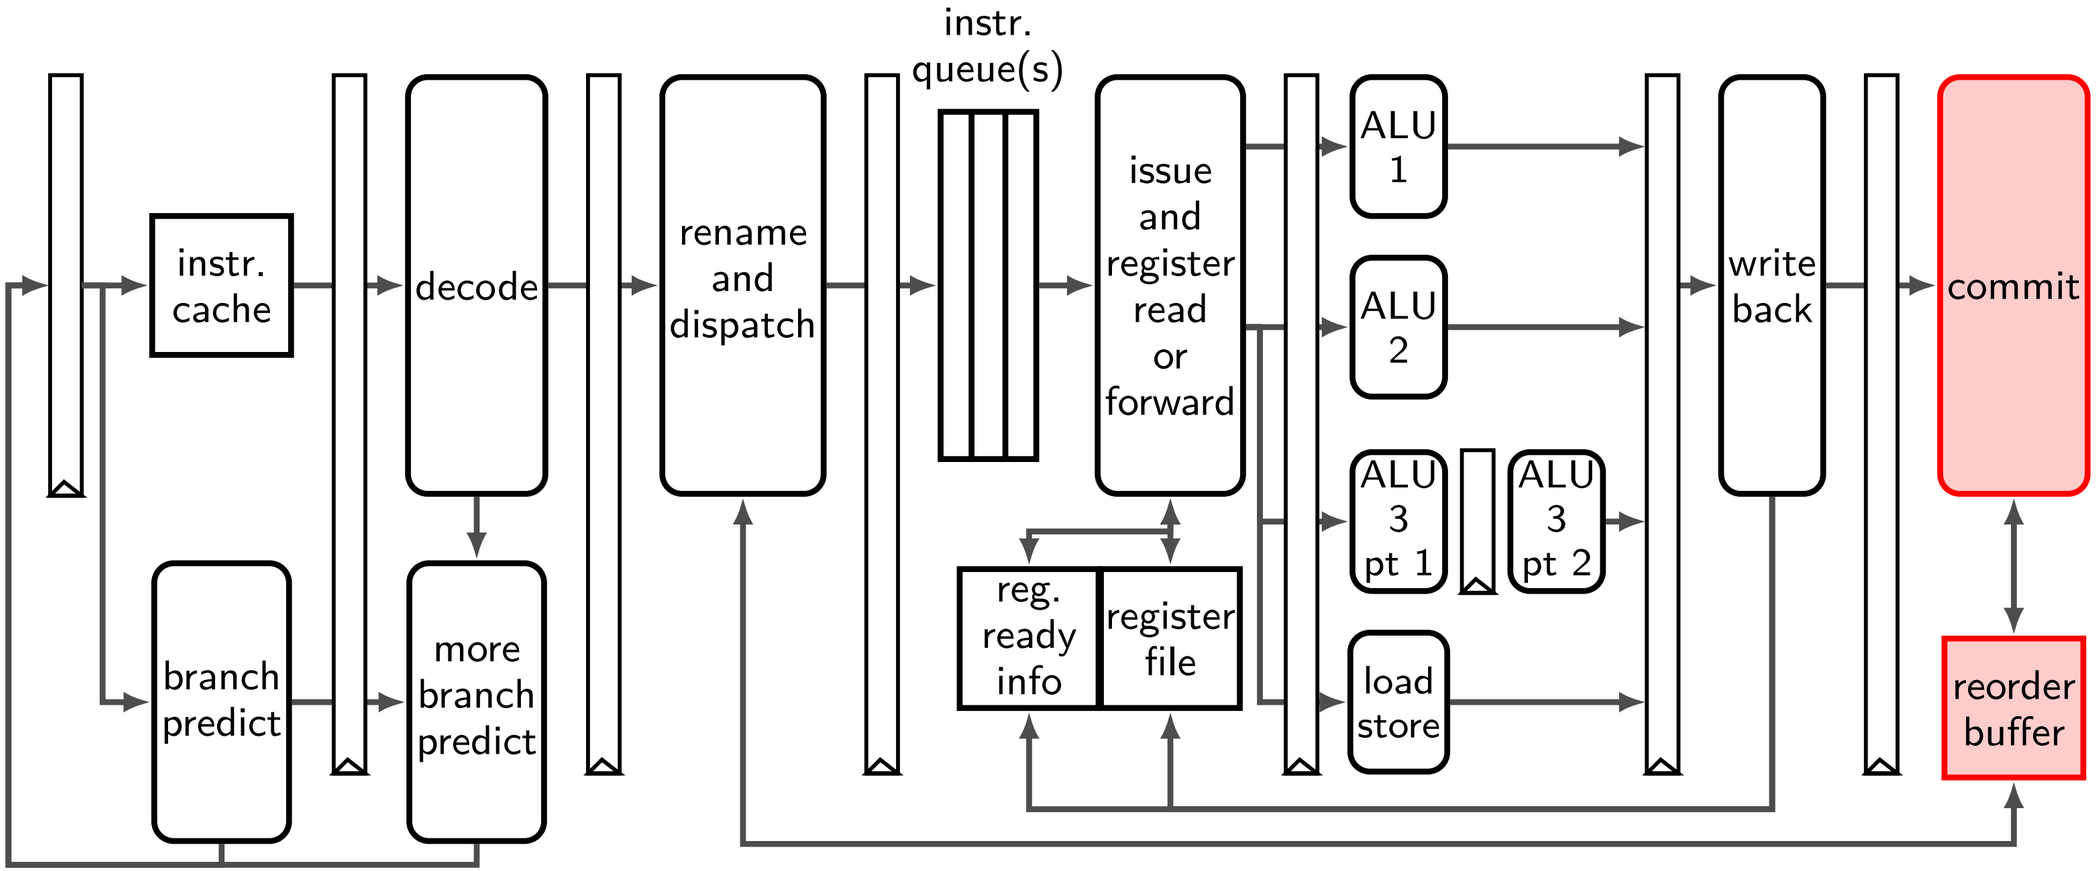
writeback to physical registers
register file typically supports writing 3+ registers at a time

an OOO pipeline (commit)



new commit (sometimes *retire*) stage finalized instruction
figures out when physical registers can be reused

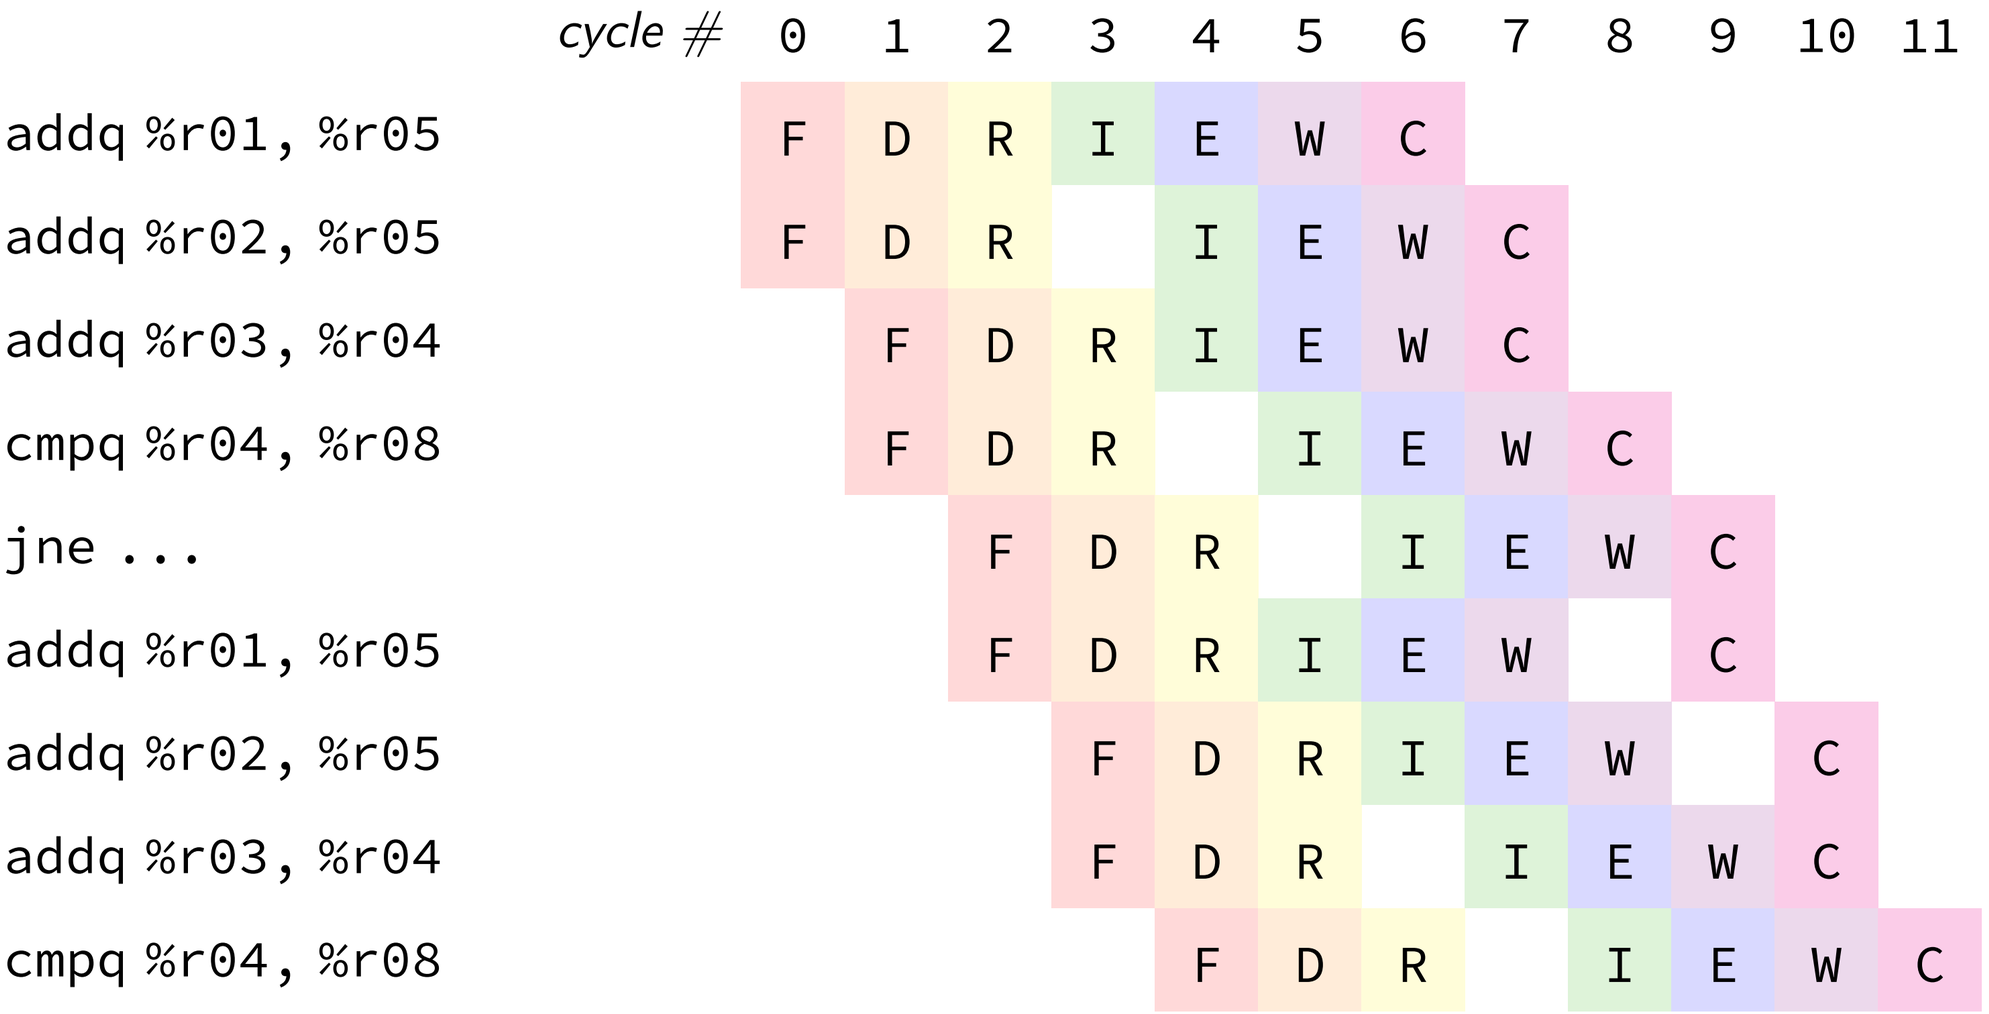
an OOO pipeline (commit)



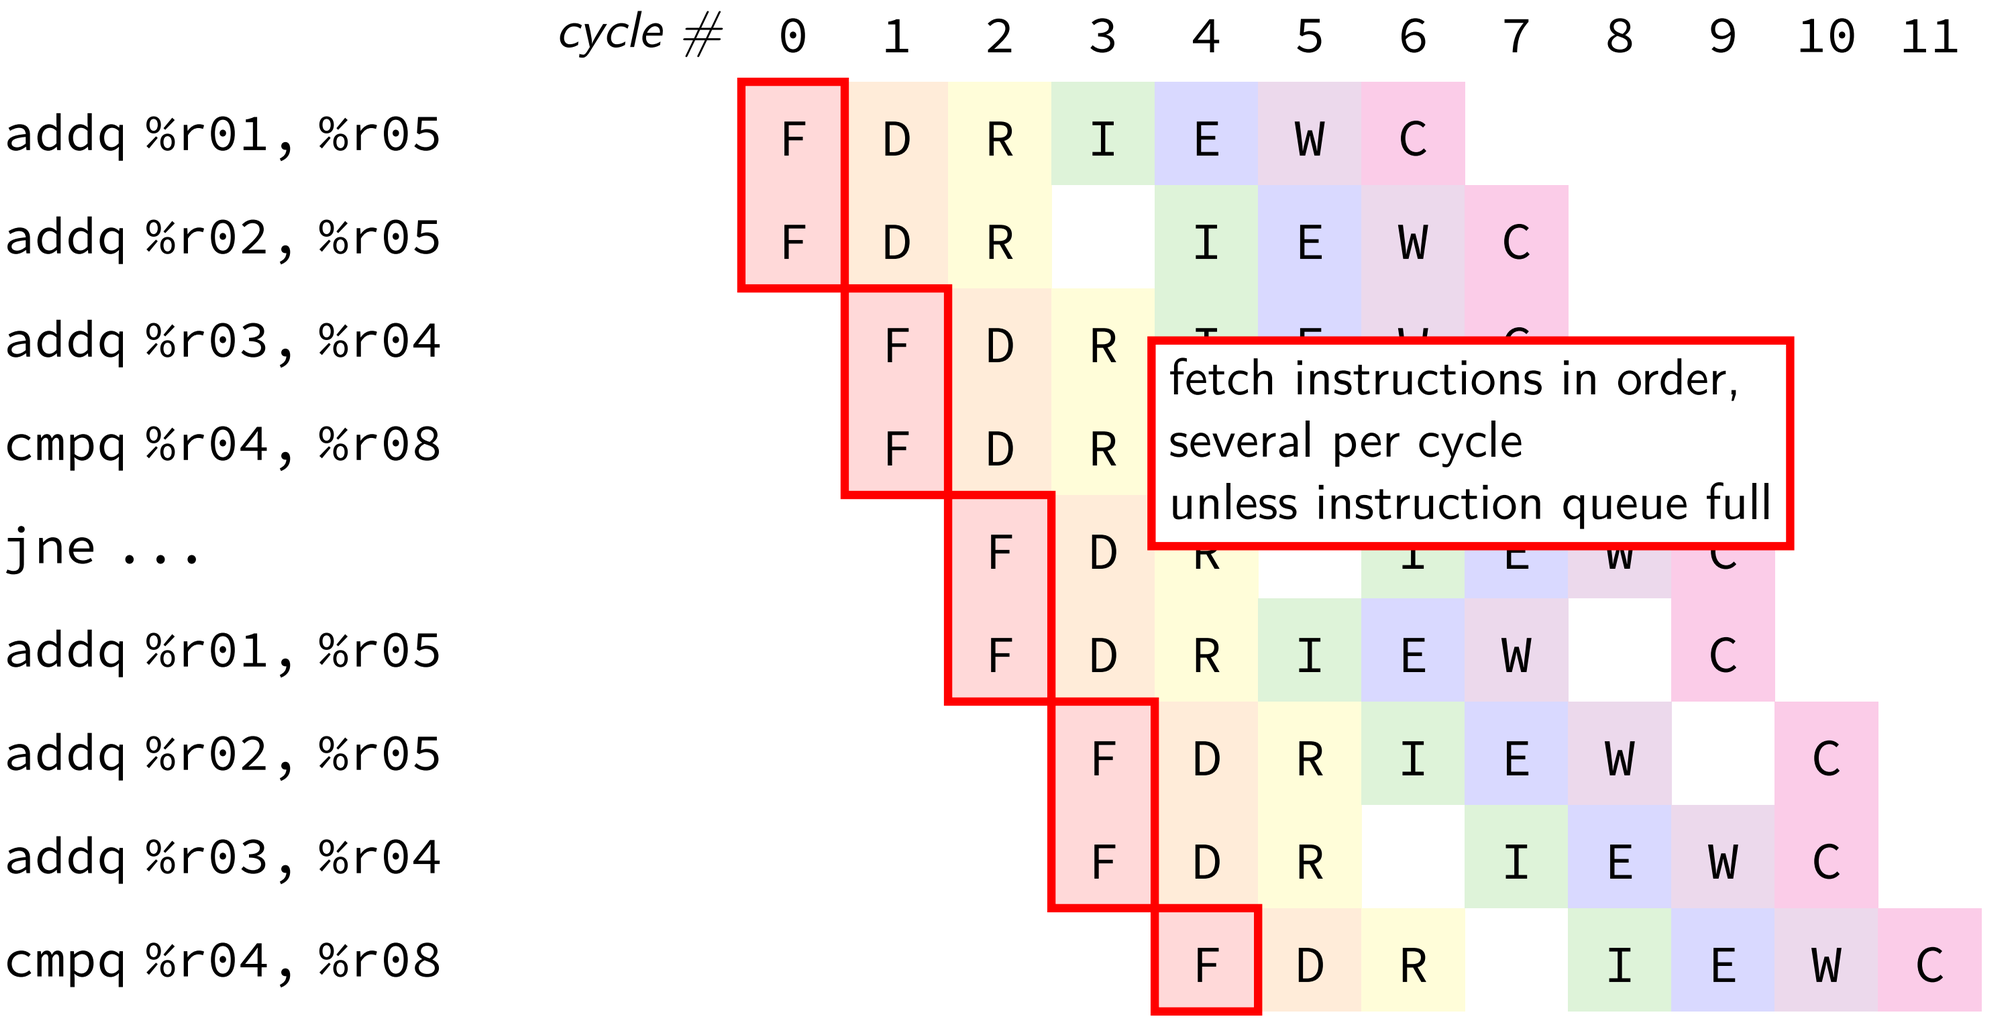
also tracks bookkeeping information if we need to undo instruction (because of branch misprediction/segfault/etc.)

an OOO pipeline diagram

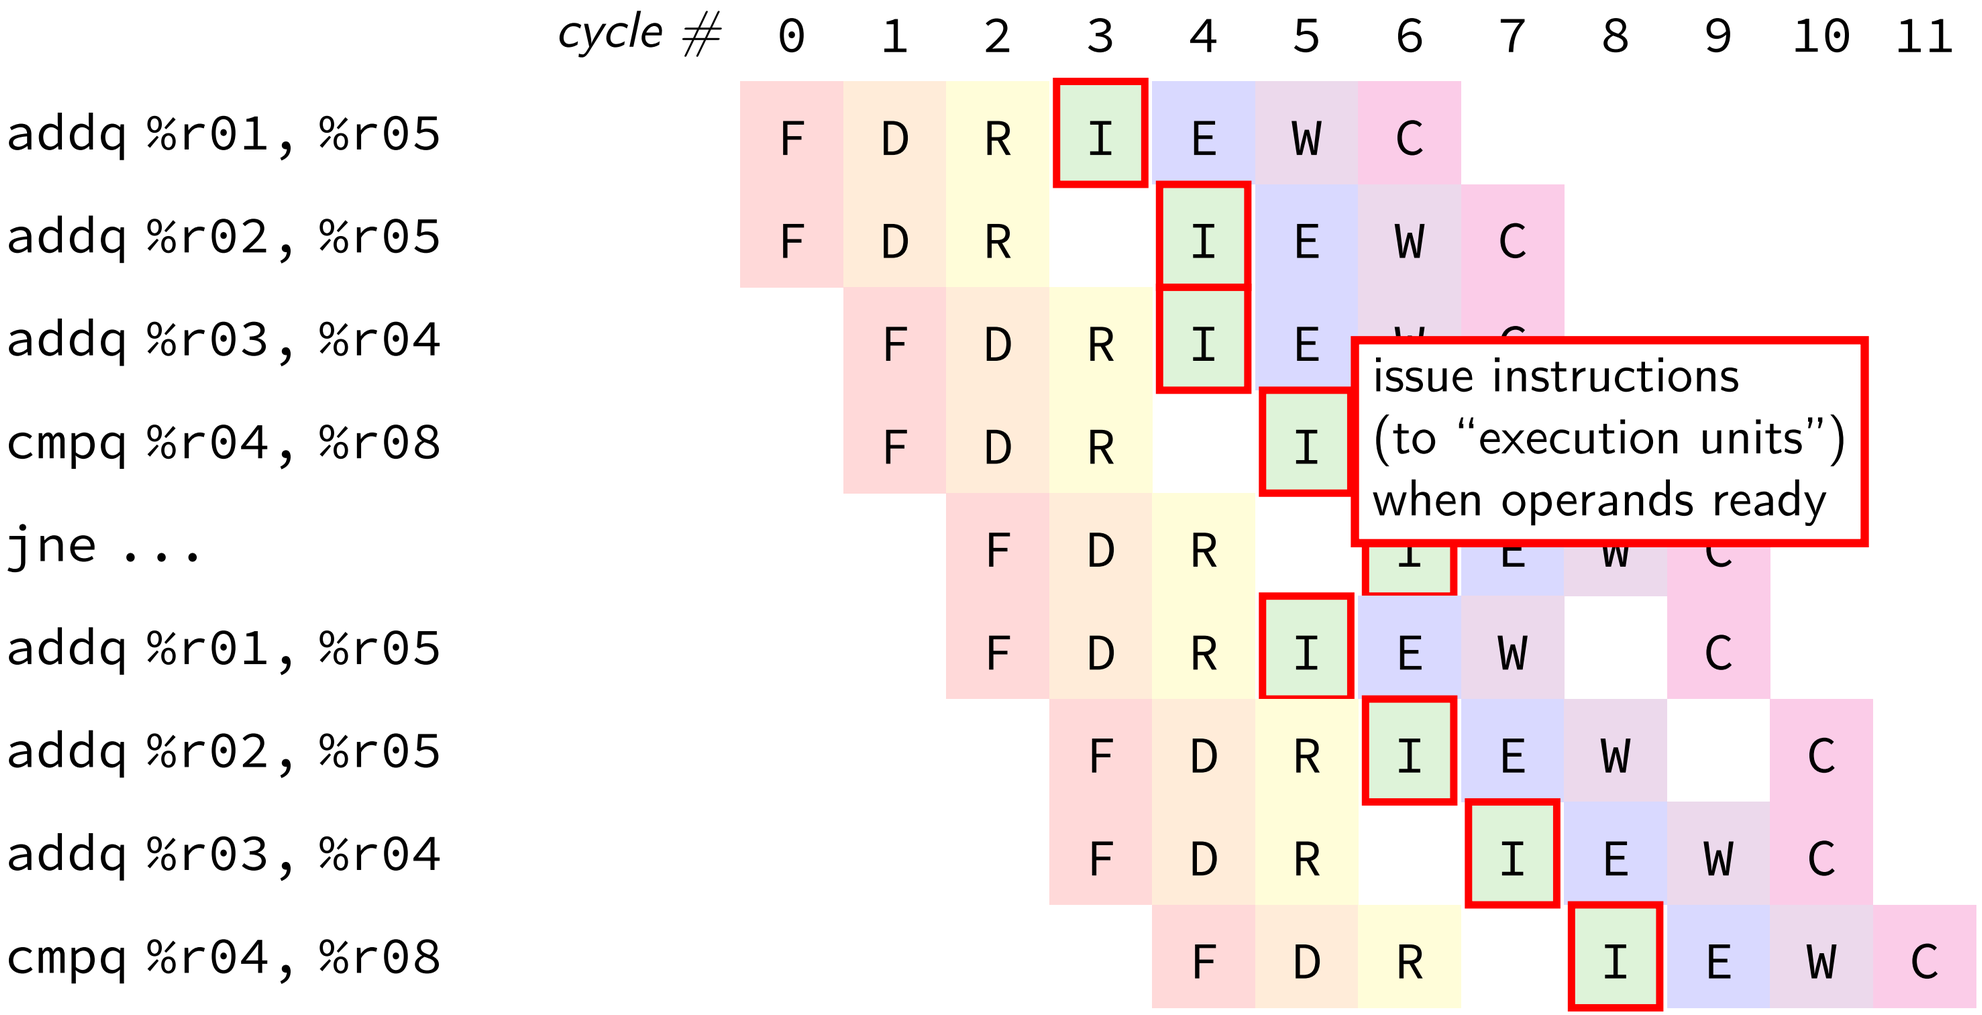
an OOO pipeline diagram



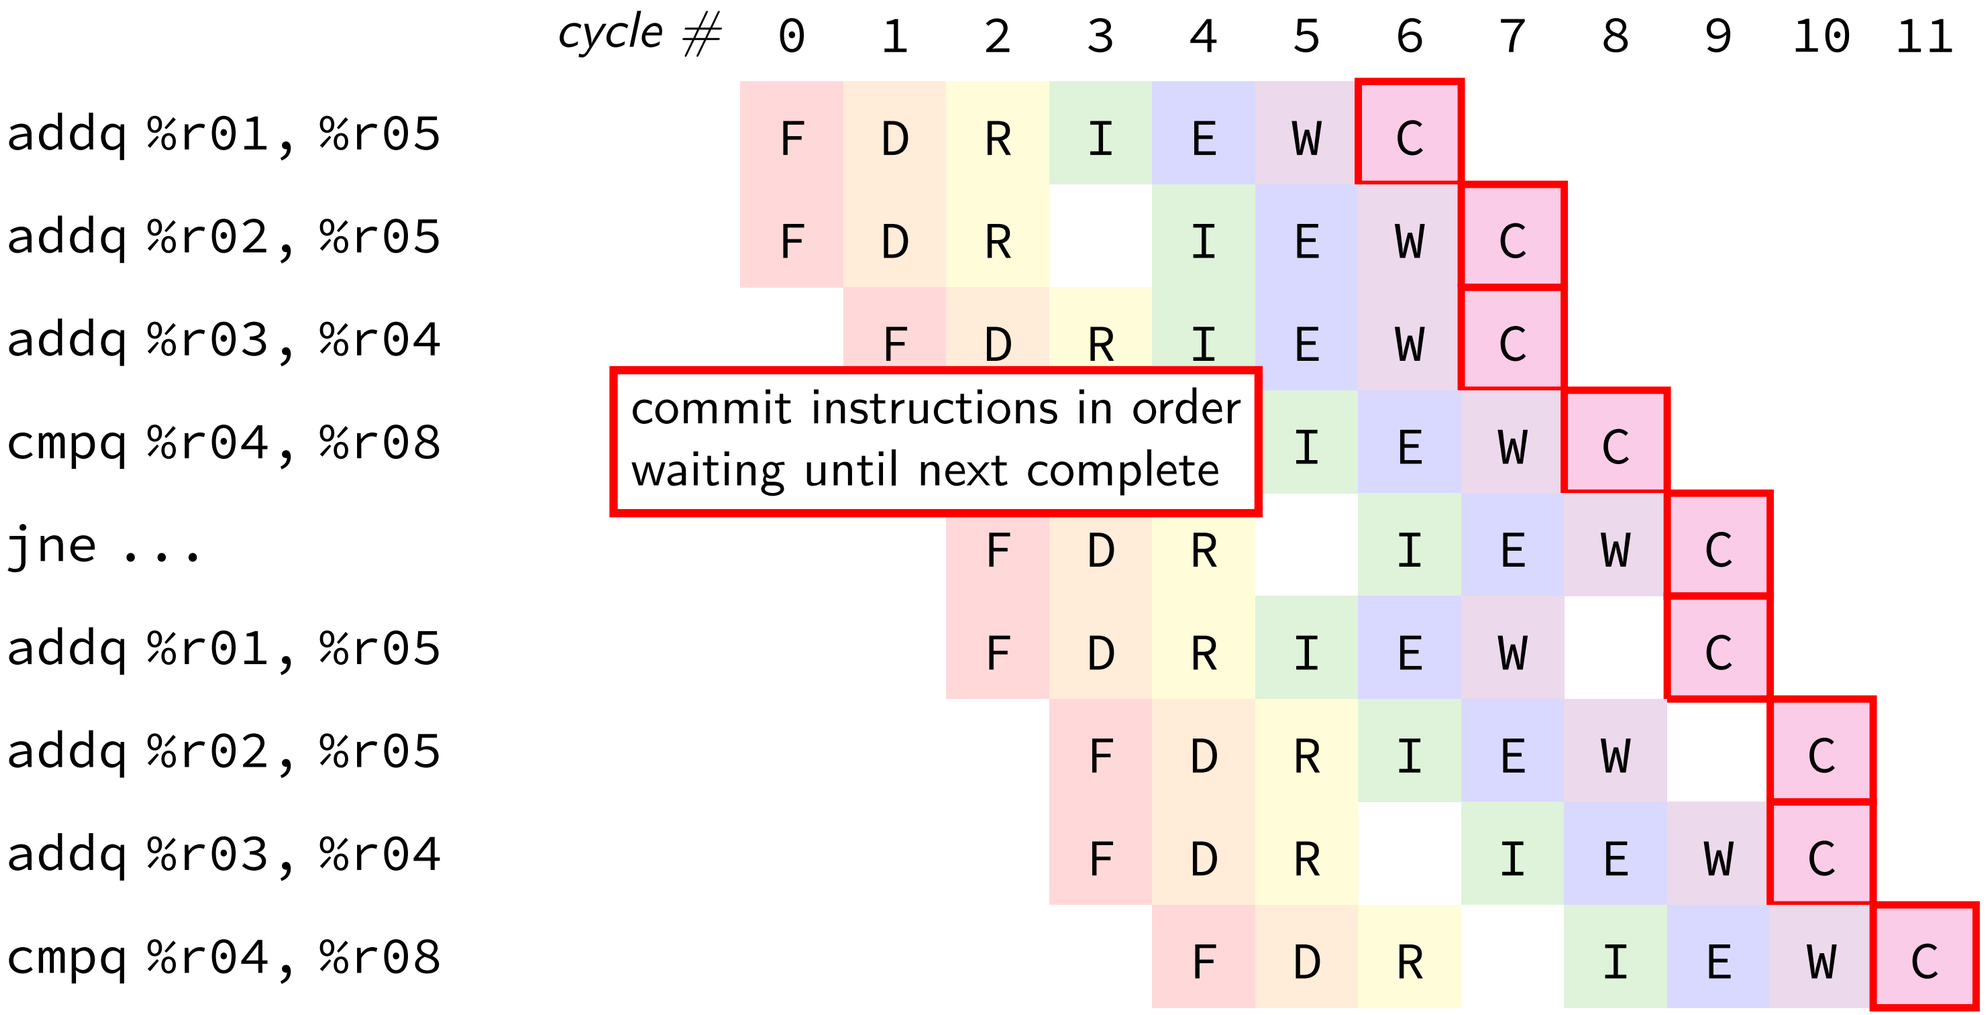
an OOO pipeline diagram



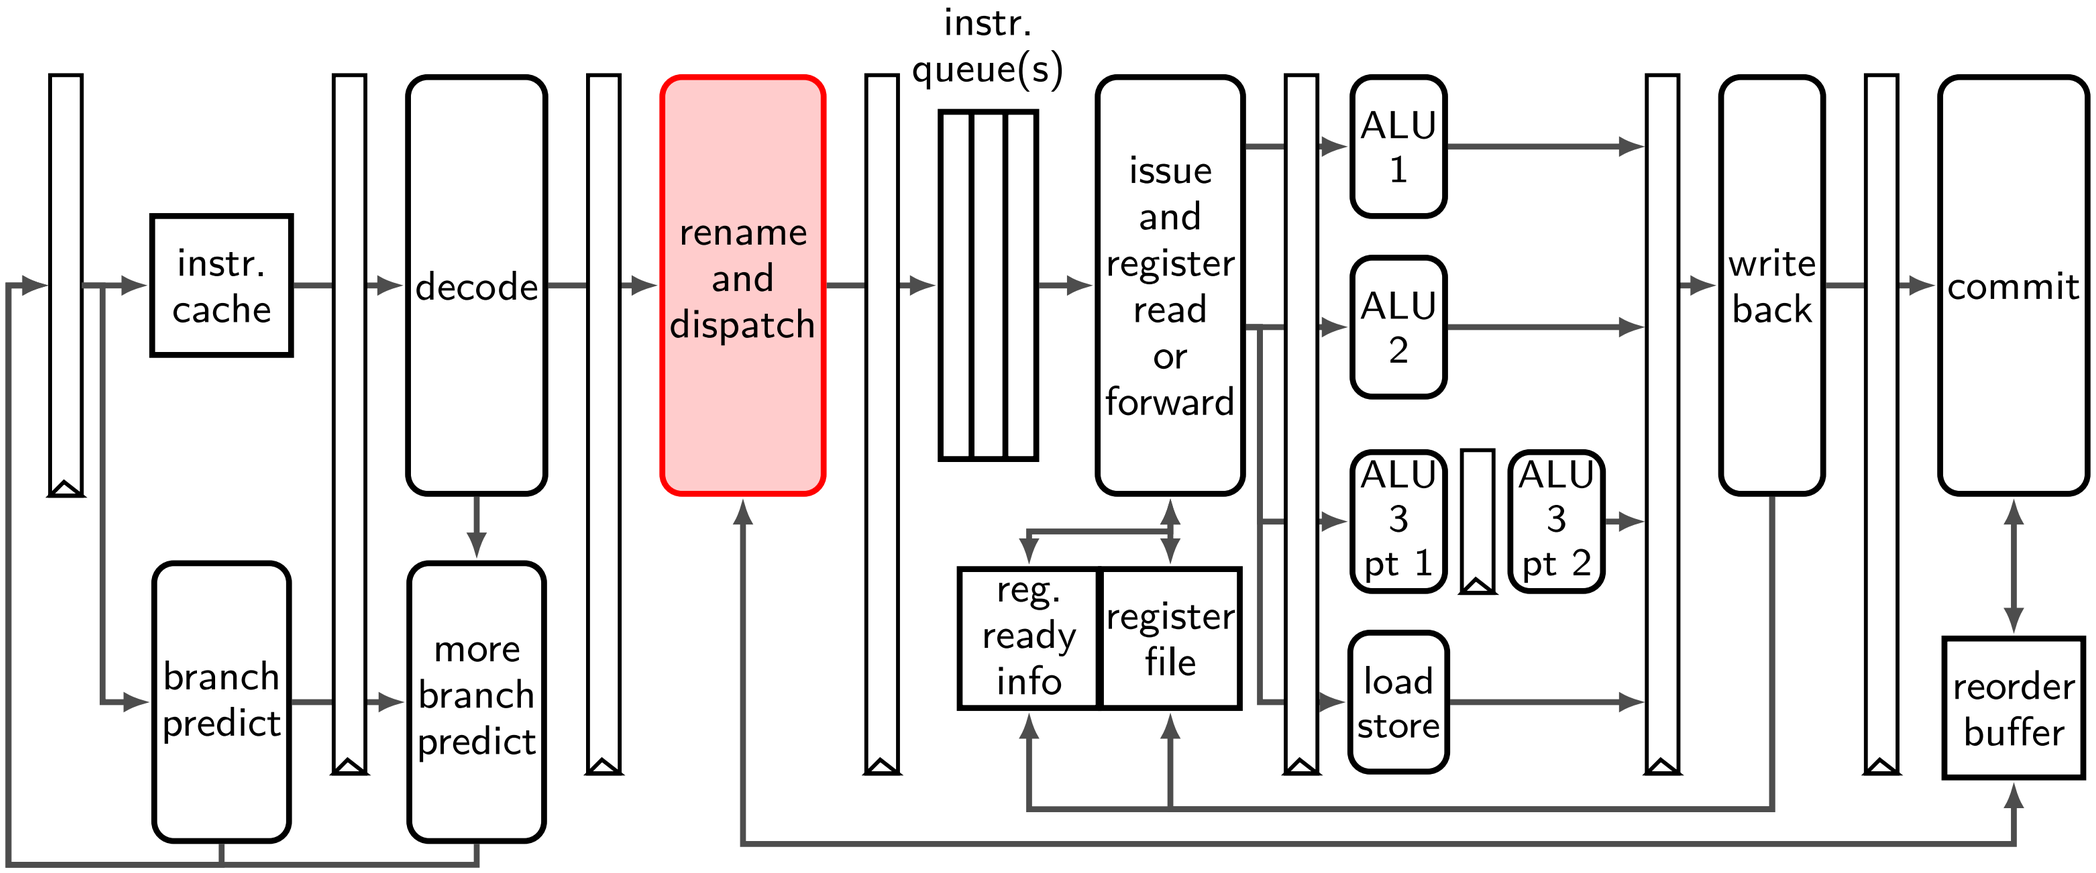
an OOO pipeline diagram



an OOO pipeline diagram



an OOO pipeline (register renaming)



register renaming

rename *architectural registers* to *physical registers*

- architectural = part of instruction set architecture

different name for each version of architectural register

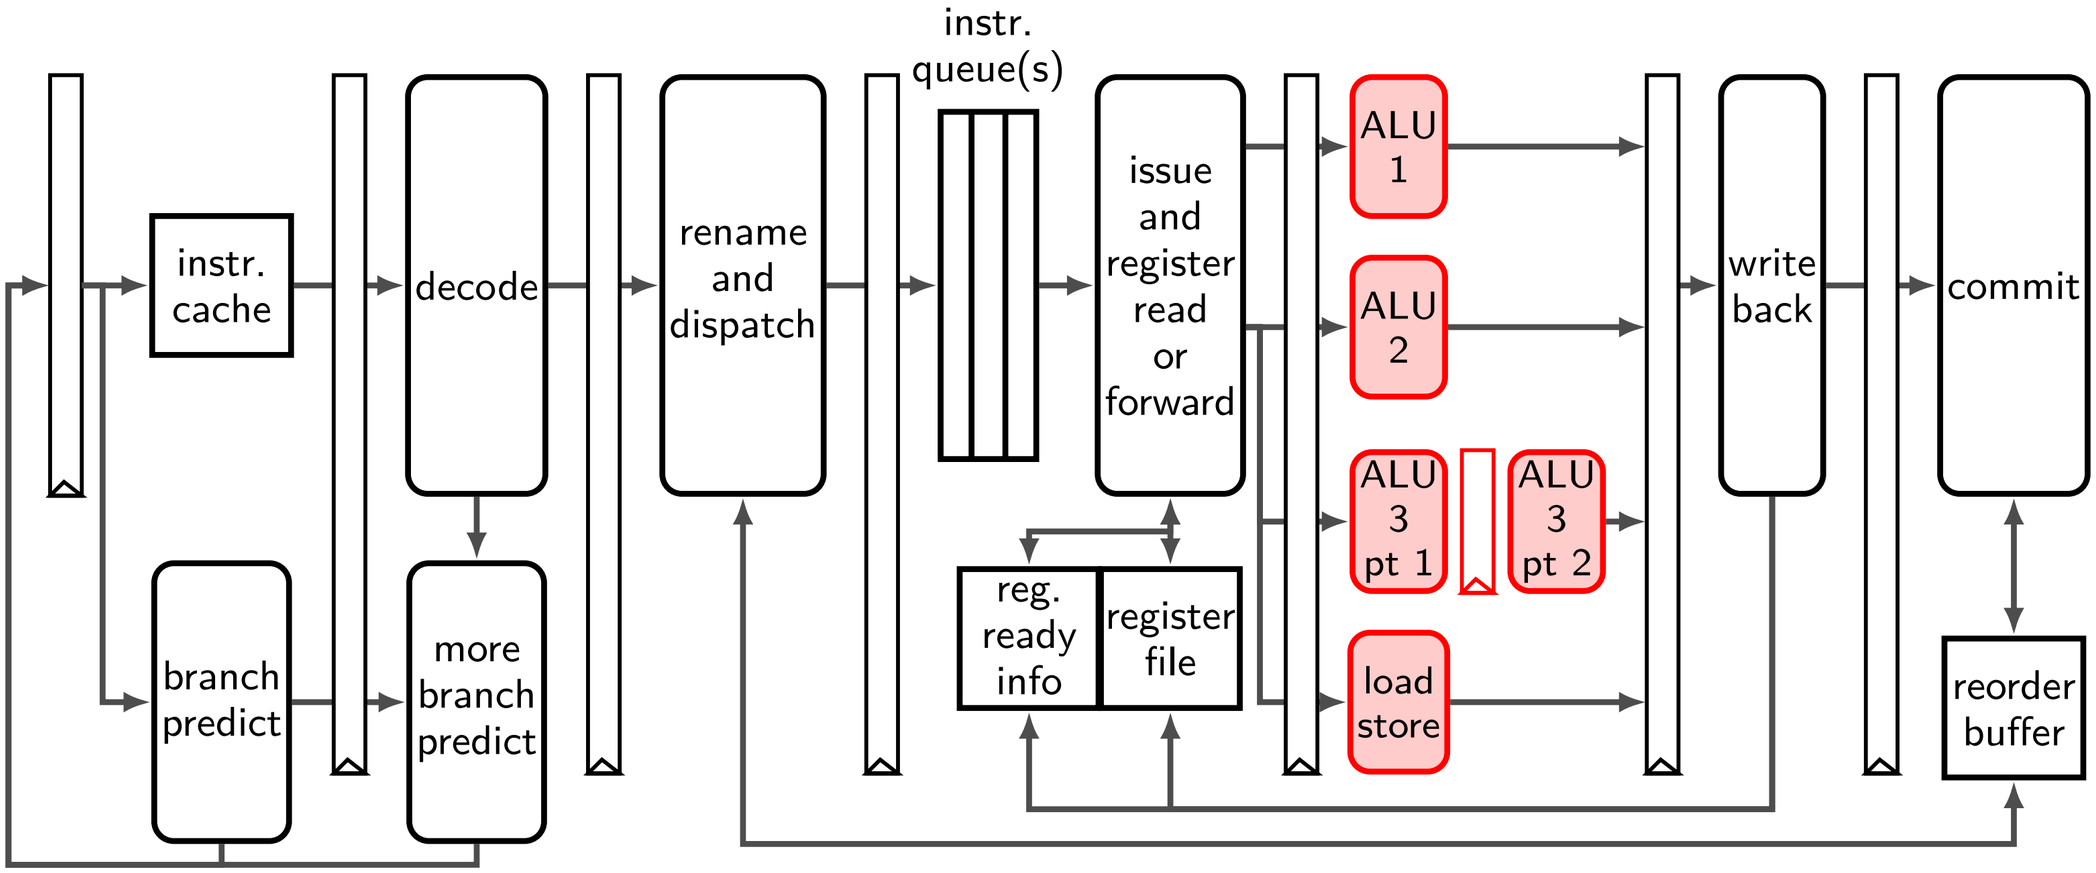
an OOO pipeline (execution units)



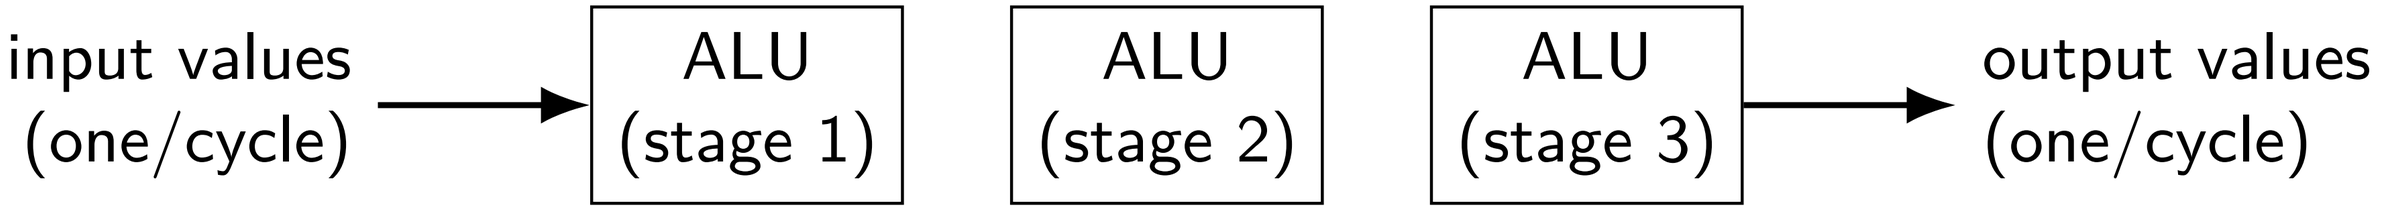
execution units AKA functional units (1a)

where actual work of instruction is done

e.g. the actual ALU, or data cache

sometimes pipelined:

(here: 1 op/cycle; 3 cycle latency)



exercise: how long to compute $A \times (B \times (C \times D))$?

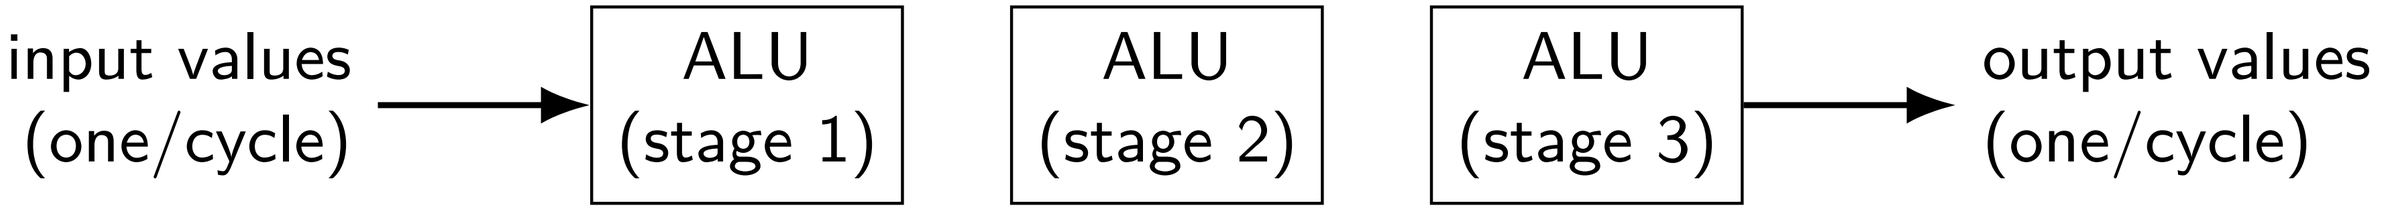
execution units AKA functional units (1a)

where actual work of instruction is done

e.g. the actual ALU, or data cache

sometimes pipelined:

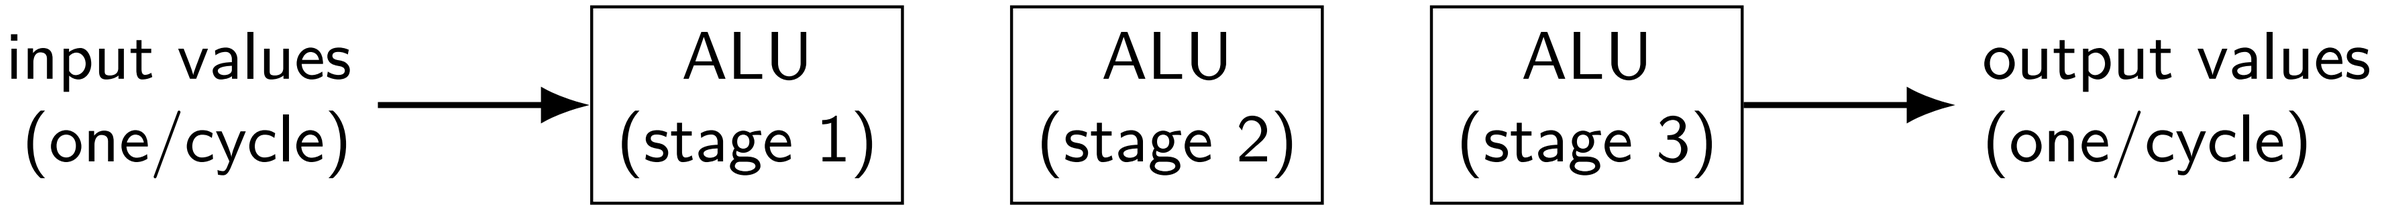
(here: 1 op/cycle; 3 cycle latency)



exercise: how long to compute $A \times (B \times (C \times D))$?

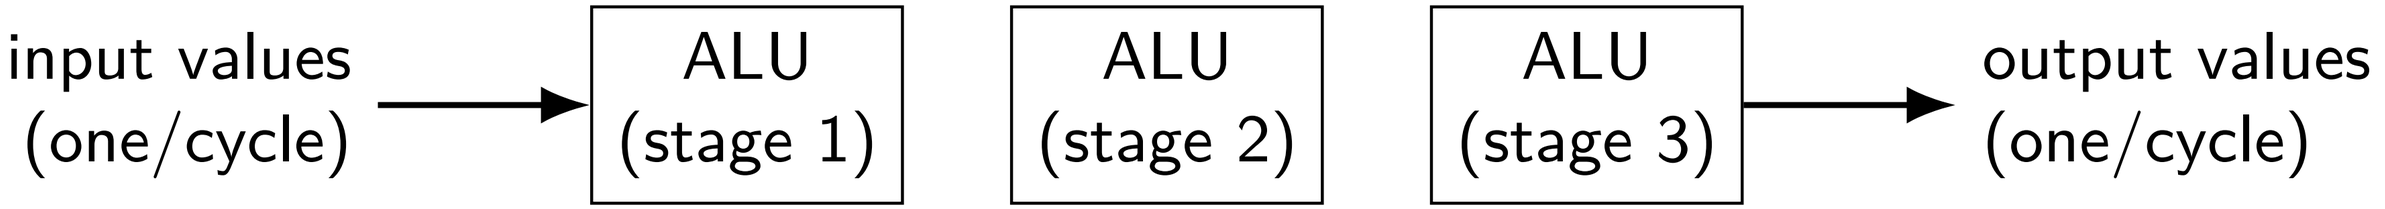
3×3 cycles + any time to forward values

execution units AKA functional units (1b)



exercise: how long to compute $(A \times B) \times (C \times D)$?

execution units AKA functional units (1b)



exercise: how long to compute $(A \times B) \times (C \times D)$?

assuming just one ALU:

	1	**2**	**3**	**4**	**5**	**6**	**7**
$A \times B$	1	2	3				
$C \times D$		1	2	3			
final					1	2	3

exercise part 2: how much would second ALU help?

execution units AKA functional units (2)

where actual work of instruction is done

e.g. the actual ALU, or data cache

sometimes unpipelined:

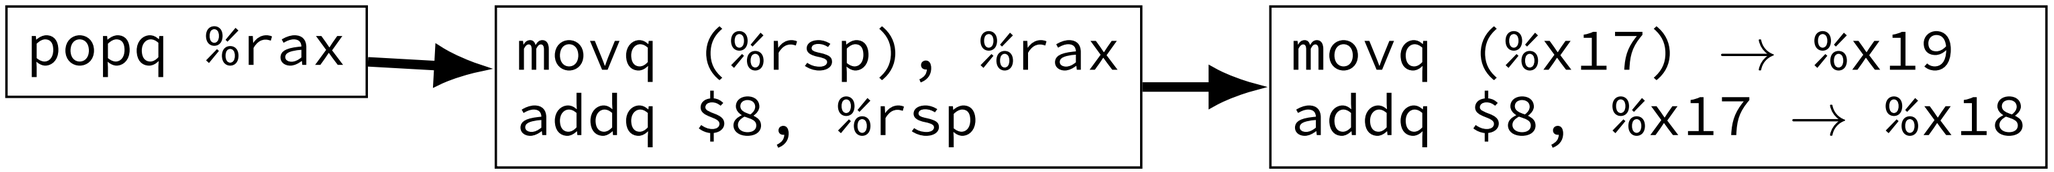
register renaming: missing pieces

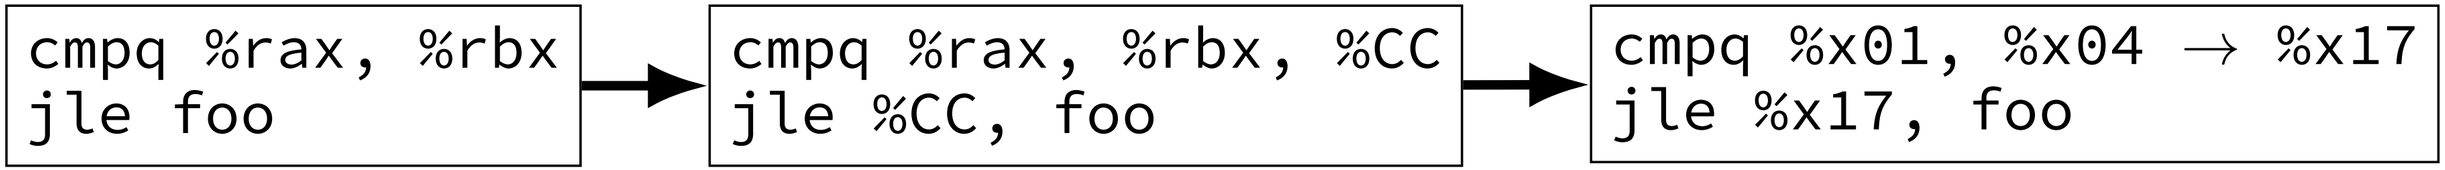
what about "hidden" inputs like `%rsp`, condition codes?

one solution: translate to intructions with additional register parameters

- making %rsp explicit parameter
- turning hidden condition codes into operands!

bonus: can also translate complex instructions to simpler ones

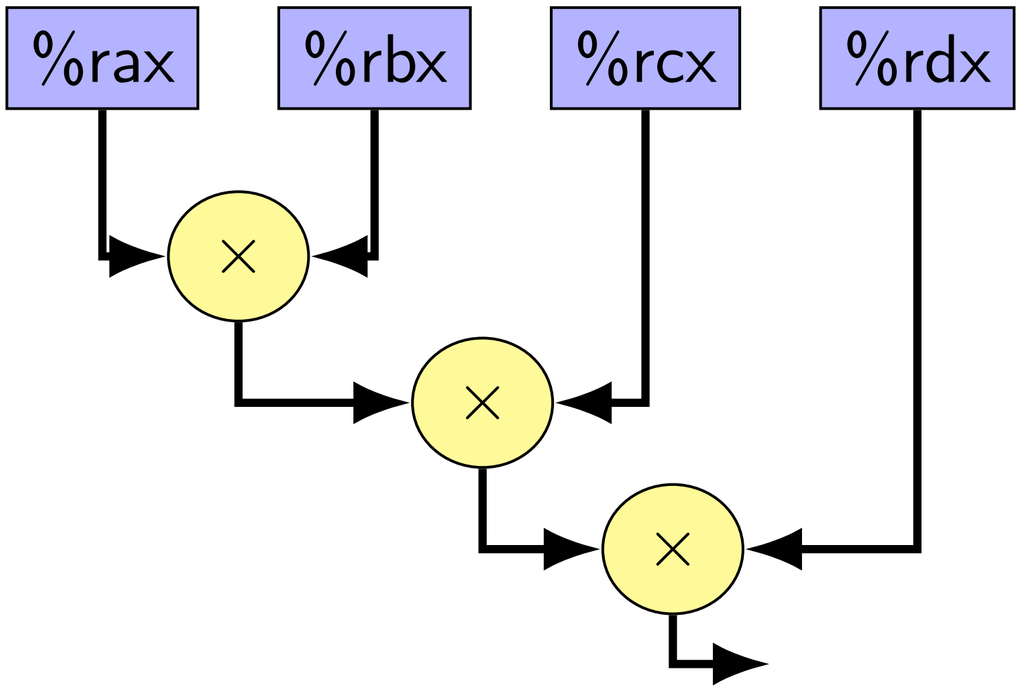




data flow visualization

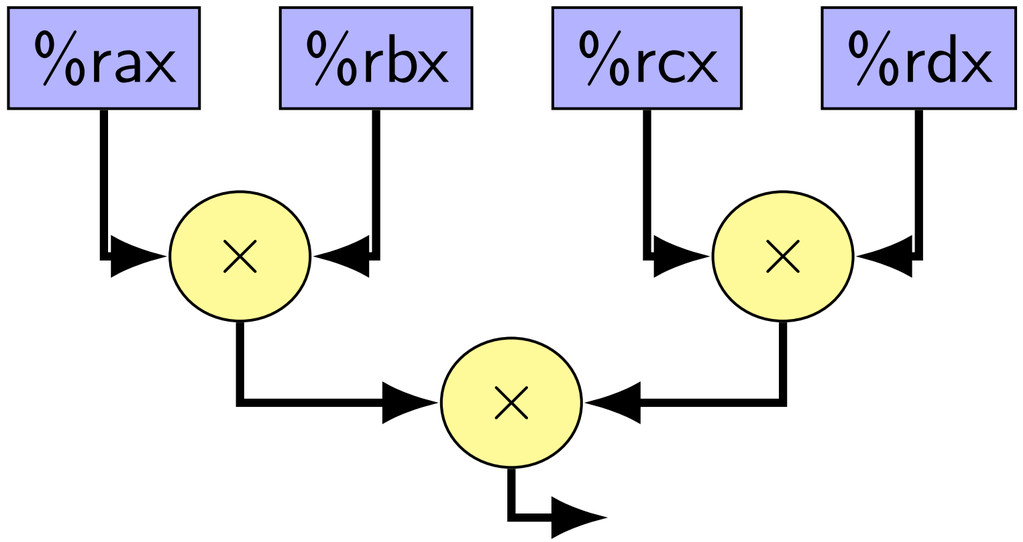
$$((a \times b) \times c) \times d$$

```
imulq %rbx, %rax
imulq %rcx, %rax
imulq %rdx, %rax
```



$$(a \times b) \times (c \times d)$$

```
imulq %rbx, %rax
imulq %rcx, %rdx
imulq %rdx, %rax
```



OOO limitations

can’t always find instructions to run

- plenty of instructions, but all depend on unfinished ones
- programmer can adjust program to help this

need to track all uncommitted instructions

- can only go so far ahead
- e.g. Intel Skylake: 224-entry reorder buffer, 168 physical registers

branch misprediction has a big cost (relative to pipelined)

- e.g. Intel Skylake: up to approx. 16 cycles (v. 2 for simple pipelined CPU)

OOO limitations

can't always find instructions to run

- plenty of instructions, but all depend on unfinished ones
- *programmer can adjust program to help this*

need to track all uncommitted instructions

- can only go so far ahead
- e.g. Intel Skylake: 224-entry reorder buffer, 168 physical registers

branch misprediction has a big cost (relative to pipelined)

- e.g. Intel Skylake: up to approx. 16 cycles (v. 2 for simple pipelined CPU)

some performance examples

some performance examples

```
example1:
    movq $10000000000, %rax
loop1:
    addq %rbx, %rcx
    decq %rax
    jge loop1
    ret
```

about 30B instructions

my desktop: approx 2.65 sec

```
example2:
    movq $10000000000, %rax
loop2:
    addq %rbx, %rcx
    addq %r8, %r9
    decq %rax
    jge loop2
    ret
```

about 40B instructions

my desktop: approx 2.65 sec

some performance examples

```
example1:
    movq $10000000000, %rax
loop1:
    addq %rbx, %rcx
    decq %rax
    jge loop1
    ret
```

about 30B instructions

my desktop: approx *2.65 sec*

```
example2:
    movq $10000000000, %rax

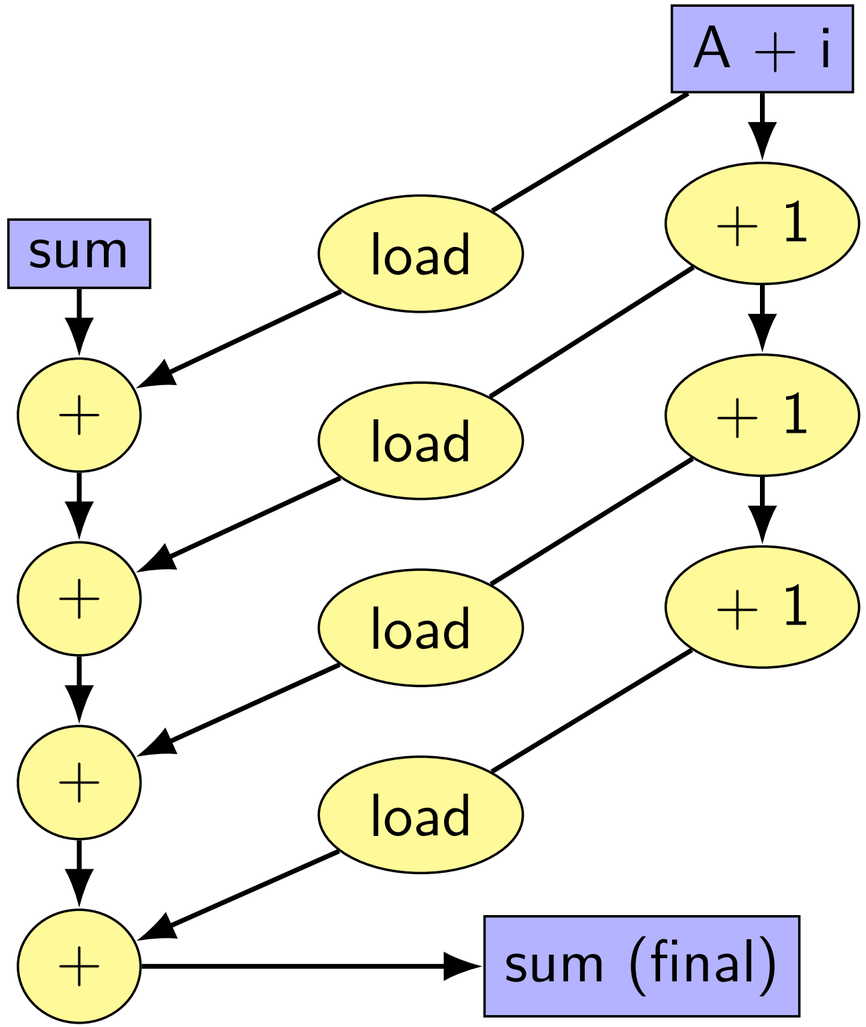
    addq %rbx, %rcx
    addq %r8, %r9
    decq %rax
    jge loop2
    ret
```

about 40B instructions

my desktop: approx *2.65 sec*

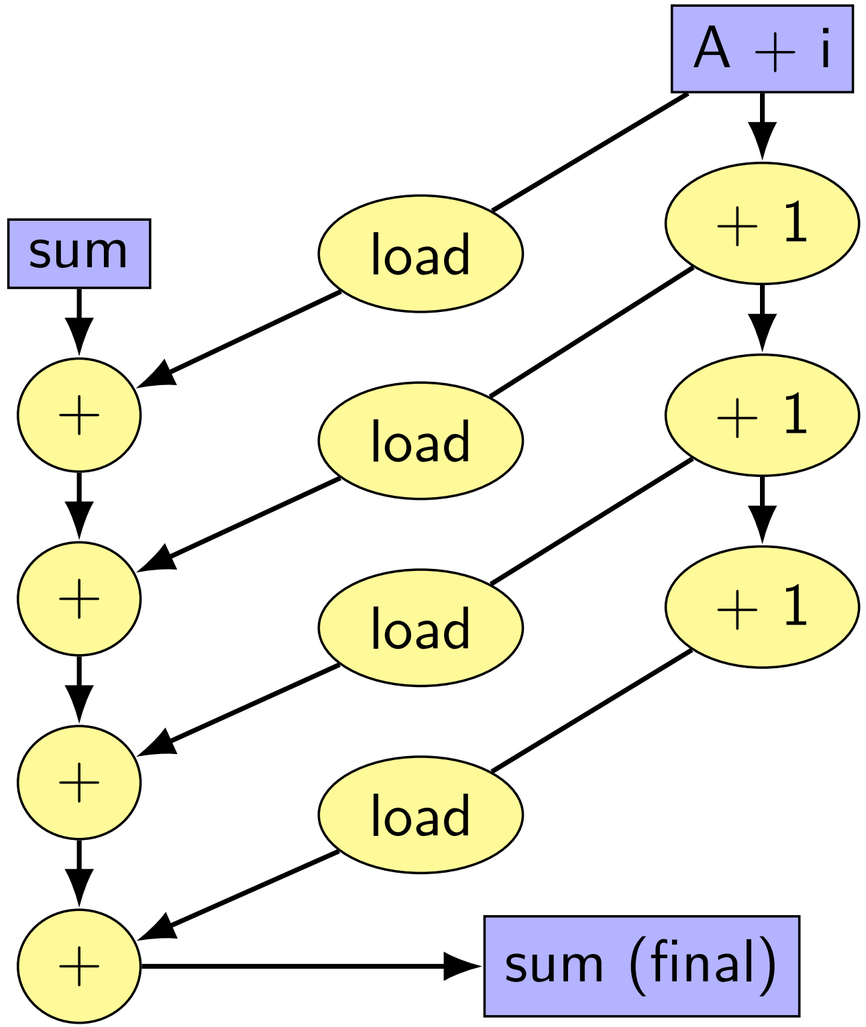
data flow model and limits

data flow model and limits



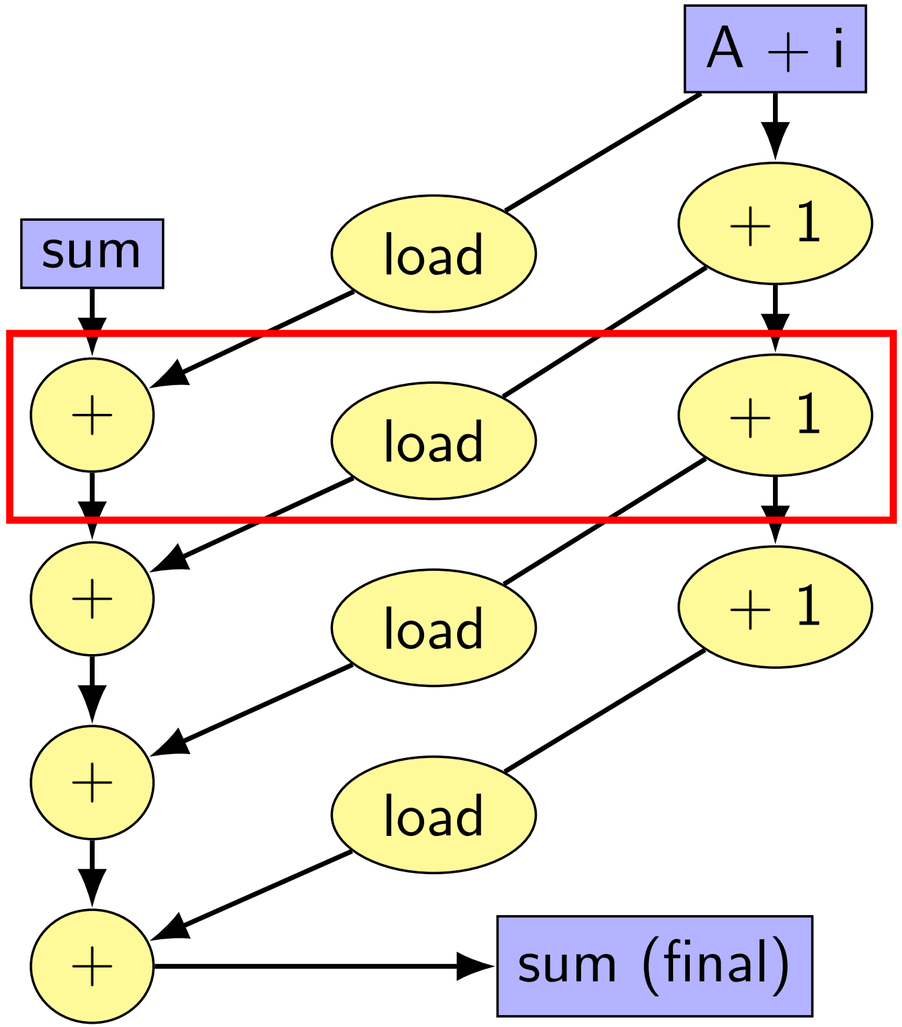
```
for (int i = 0; i < N; i += K) {
        sum += A[i];
        sum += A[i+1];
        …
}
```

data flow model and limits



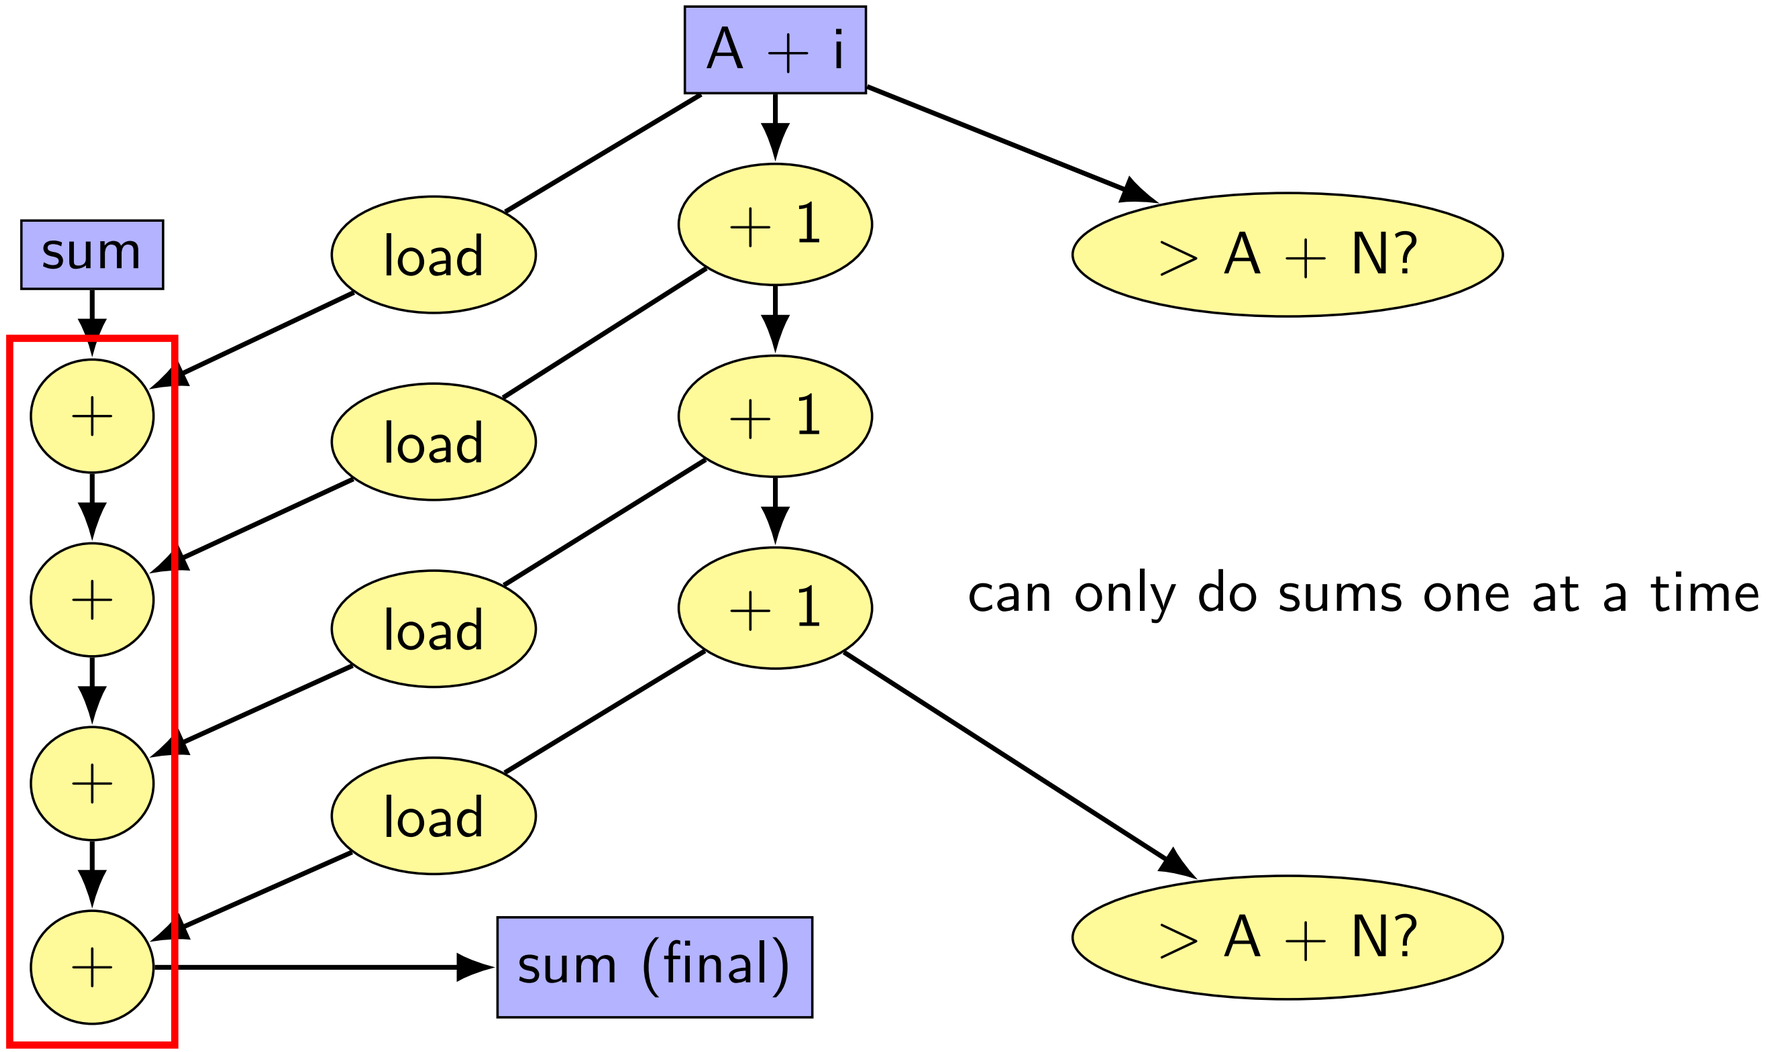
each yellow box = instruction
arrows = dependences
instructions only executed when dependencies ready

data flow model and limits



three ops/cycle (*if* each one cycle)

data flow model and limits



can only do sums one at a time

Backup slides

backup slides

data flow model and limits (1)

data flow model and limits (1)

Intel Skylake OOO design

2015 Intel design — codename ‘Skylake’

94-entry instruction queue-equivalent

168 physical integer registers

168 physical floating point registers

4 ALU functional units

- but some can handle more/different types of operations than others

2 load functional units

- but pipelined: supports multiple pending cache misses in parallel

1 store functional unit

224-entry reorder buffer

- determines how far ahead branch mispredictions, etc. can happen

indirect branch prediction

`jmp *%rax` or `jmp *(%rax, %rcx, 8)` or `call *%rax` or ...

- example: implementing switch statement
- example: implementing polymorphic method call

want to predict *target address*

BTB could store one possibility

really want to take advantage of context

- example: guess whether we'll call Rectangle.GetArea or Circle.GetArea

prediction idea: instead of tables containing taken/not taken...

... have table containing predicted target

- one implementation: hashtable keyed by recent branches taken

better? alternatives

can take snapshots of register map on each branch

- don’t need to reconstruct the table
- (but how to efficiently store them)

can reconstruct register map before we commit the branch instruction

- need to let reorder buffer be accessed even more?

can track more/different information in reorder buffer

the open-source BROOM pipeline

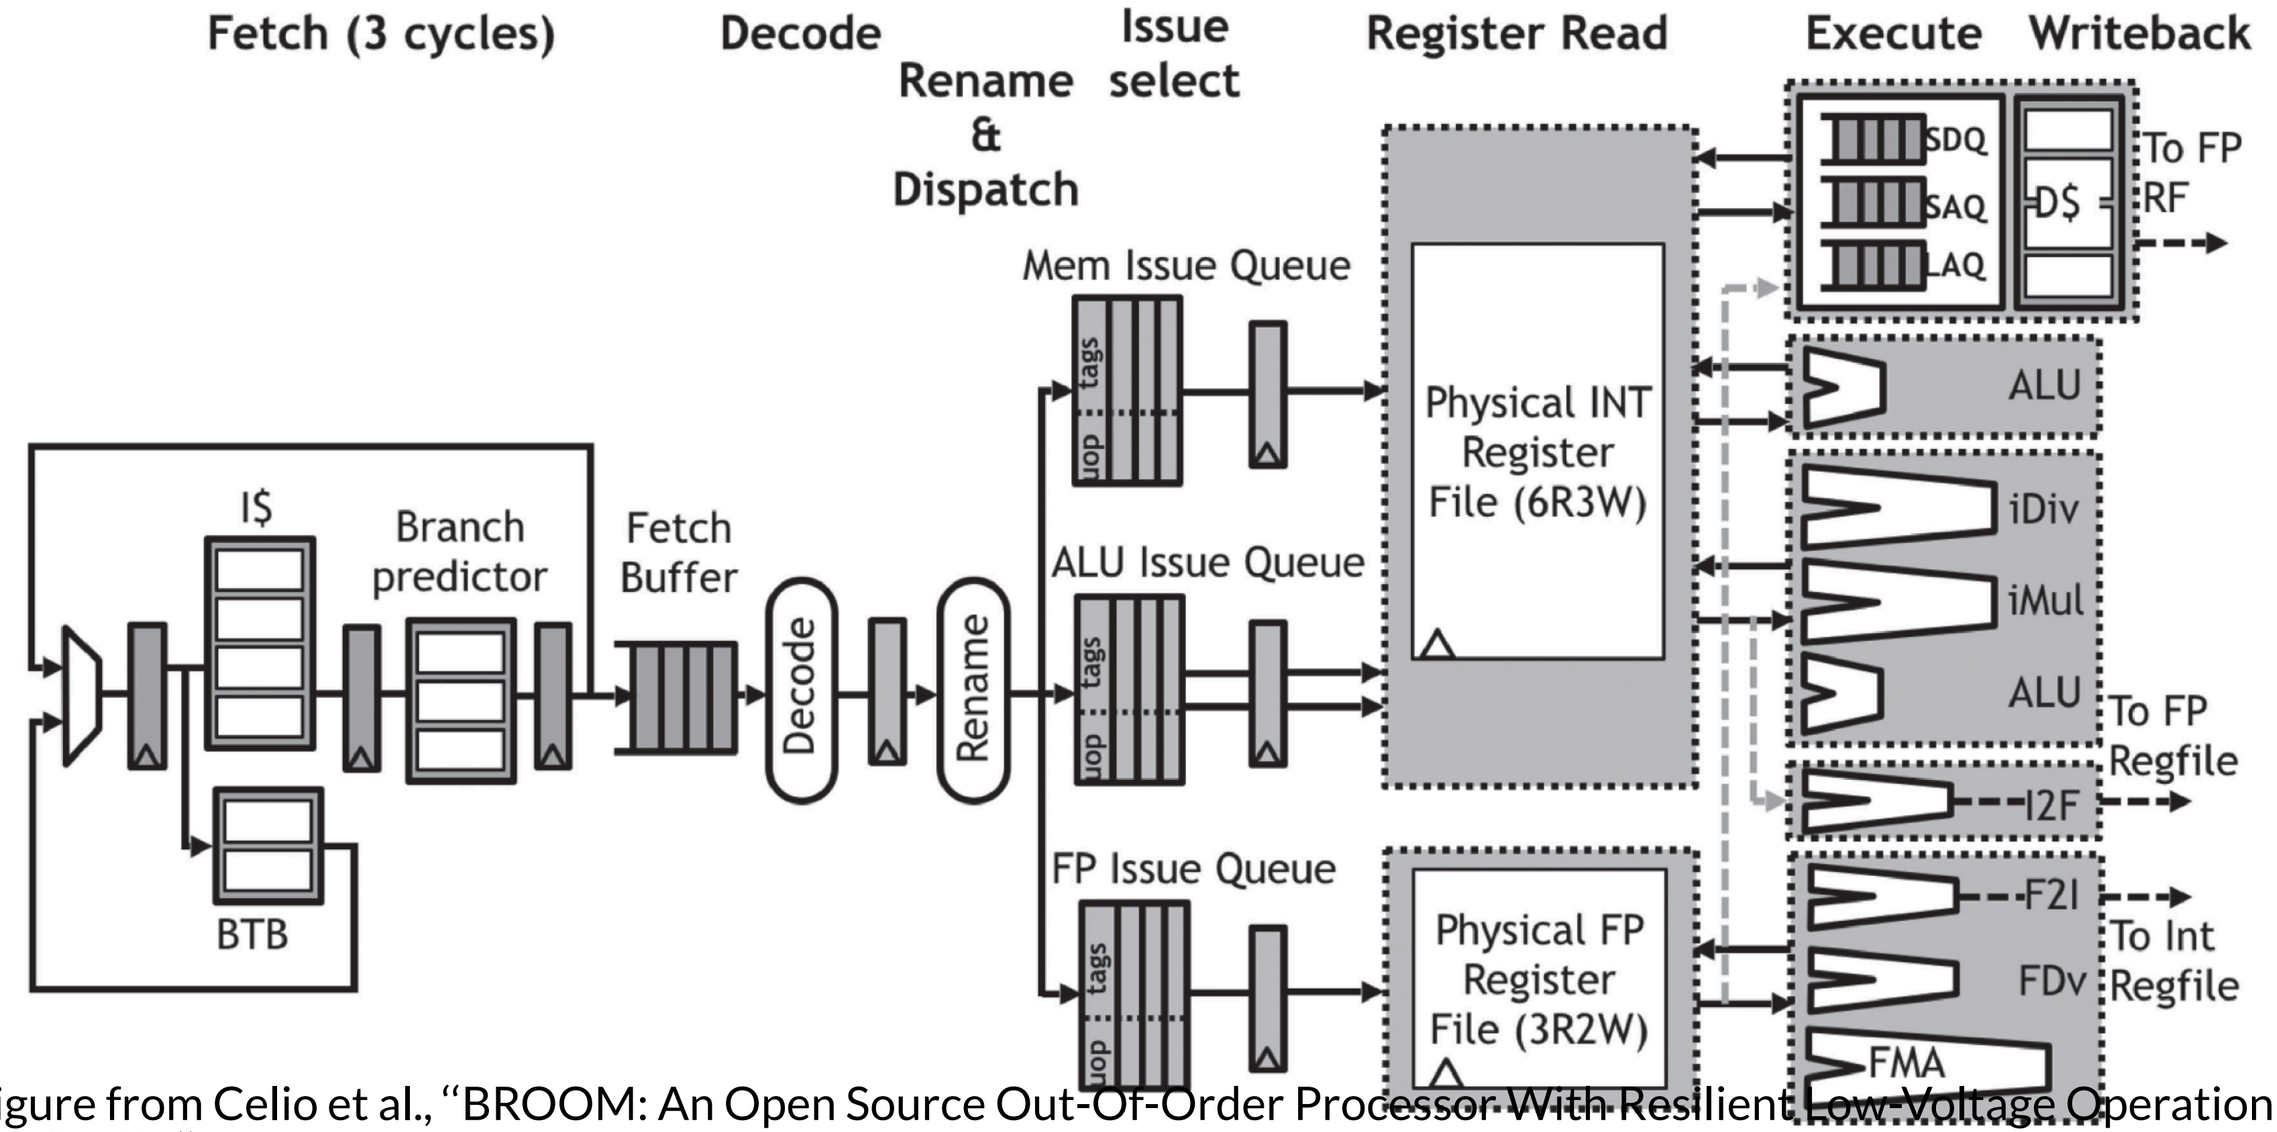

Figure from Celio et al., "BROOM: An Open Source Out-Of-Order Processor With Resilient Low-Voltage Operation in 28-nm CMOS"

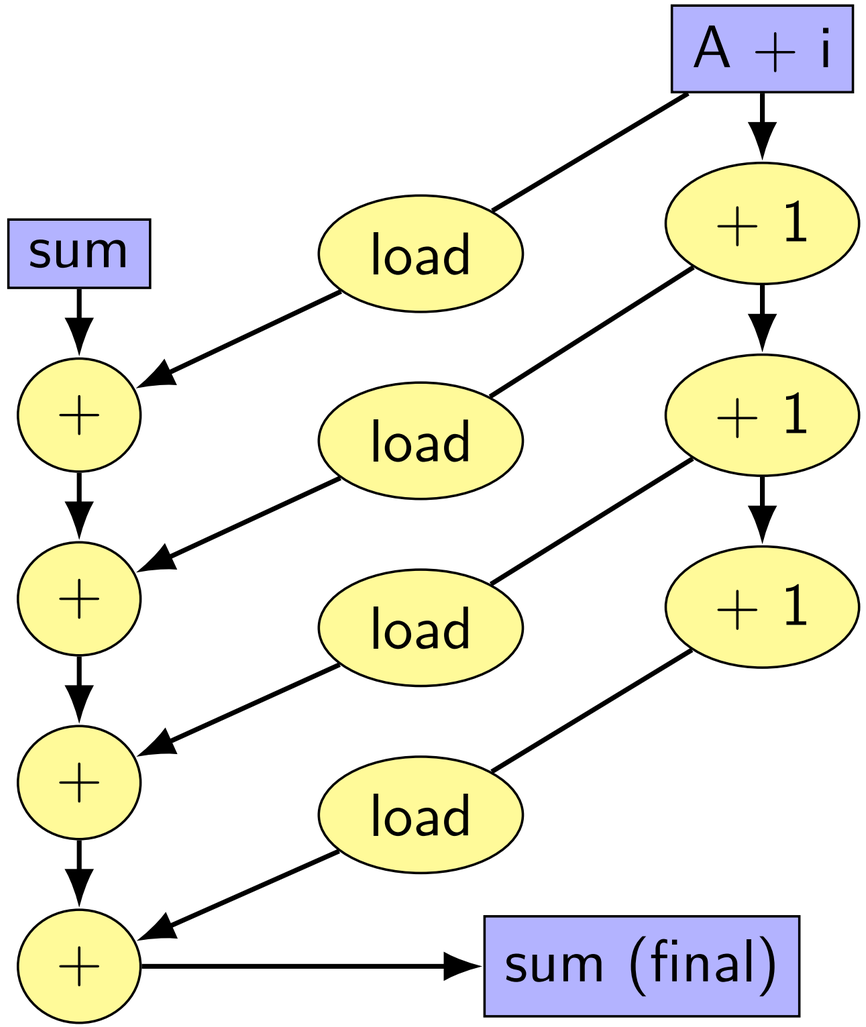
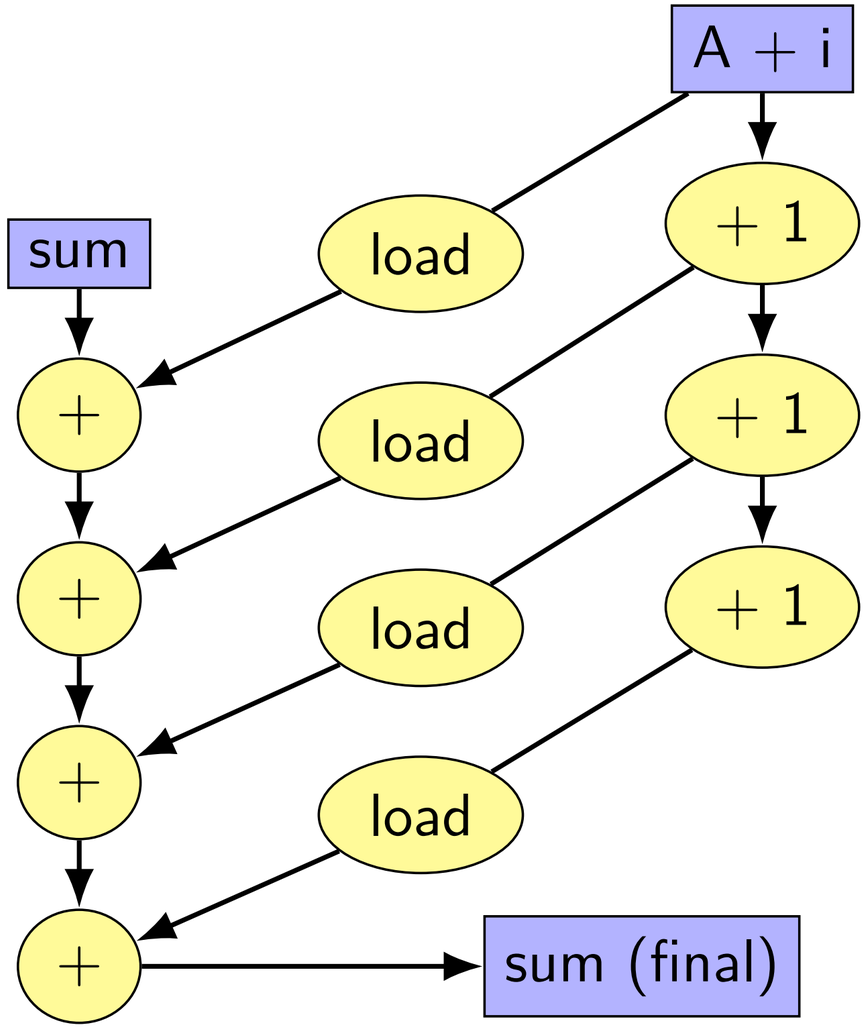
data flow model and limits

data flow model and limits



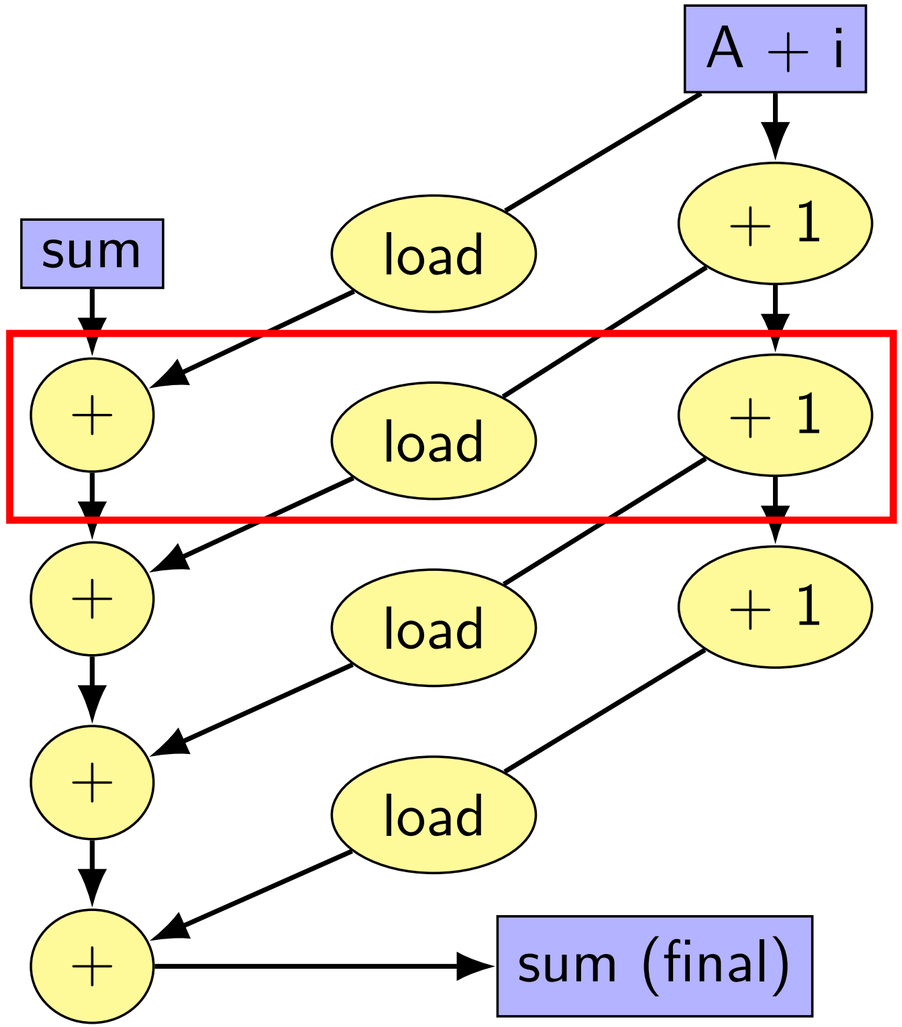
```
for (int i = 0; i < N; i += K) {
        sum += A[i];
        sum += A[i+1];
        …
}
```

data flow model and limits



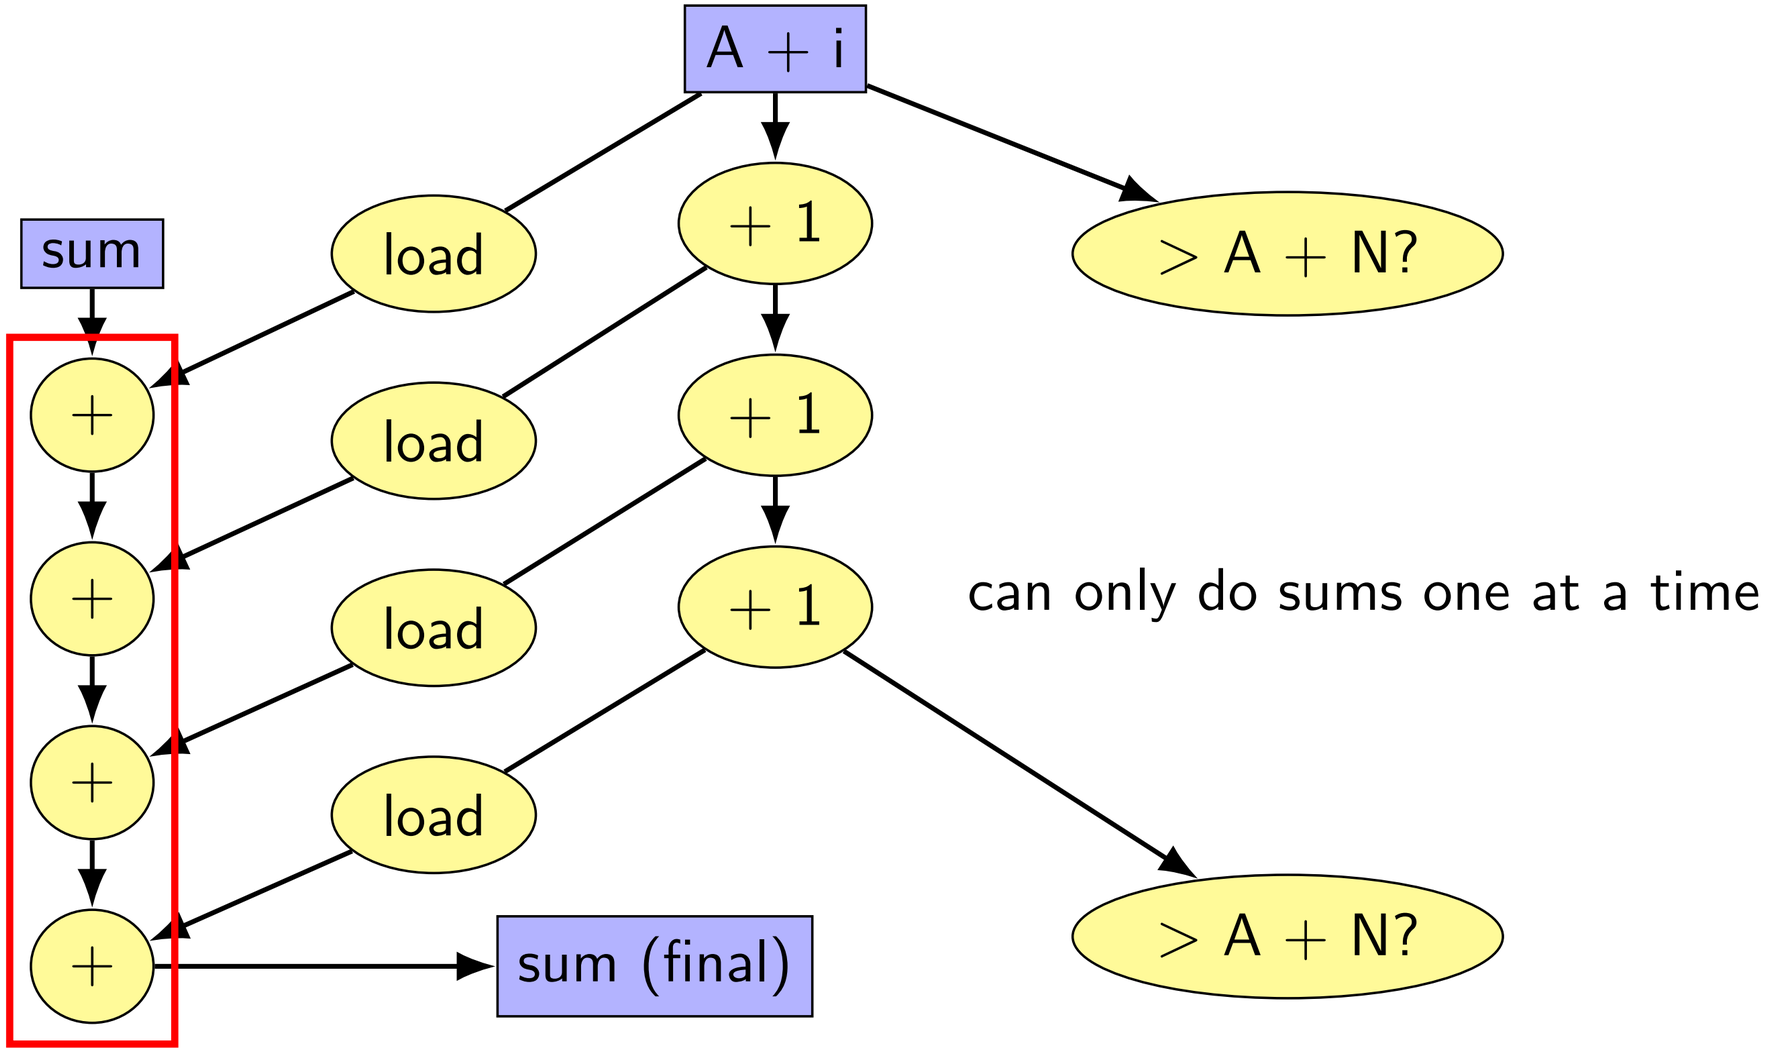
each yellow box = instruction
arrows = dependences
instructions only executed when dependencies ready

data flow model and limits



three ops/cycle (*if* each one cycle)

data flow model and limits



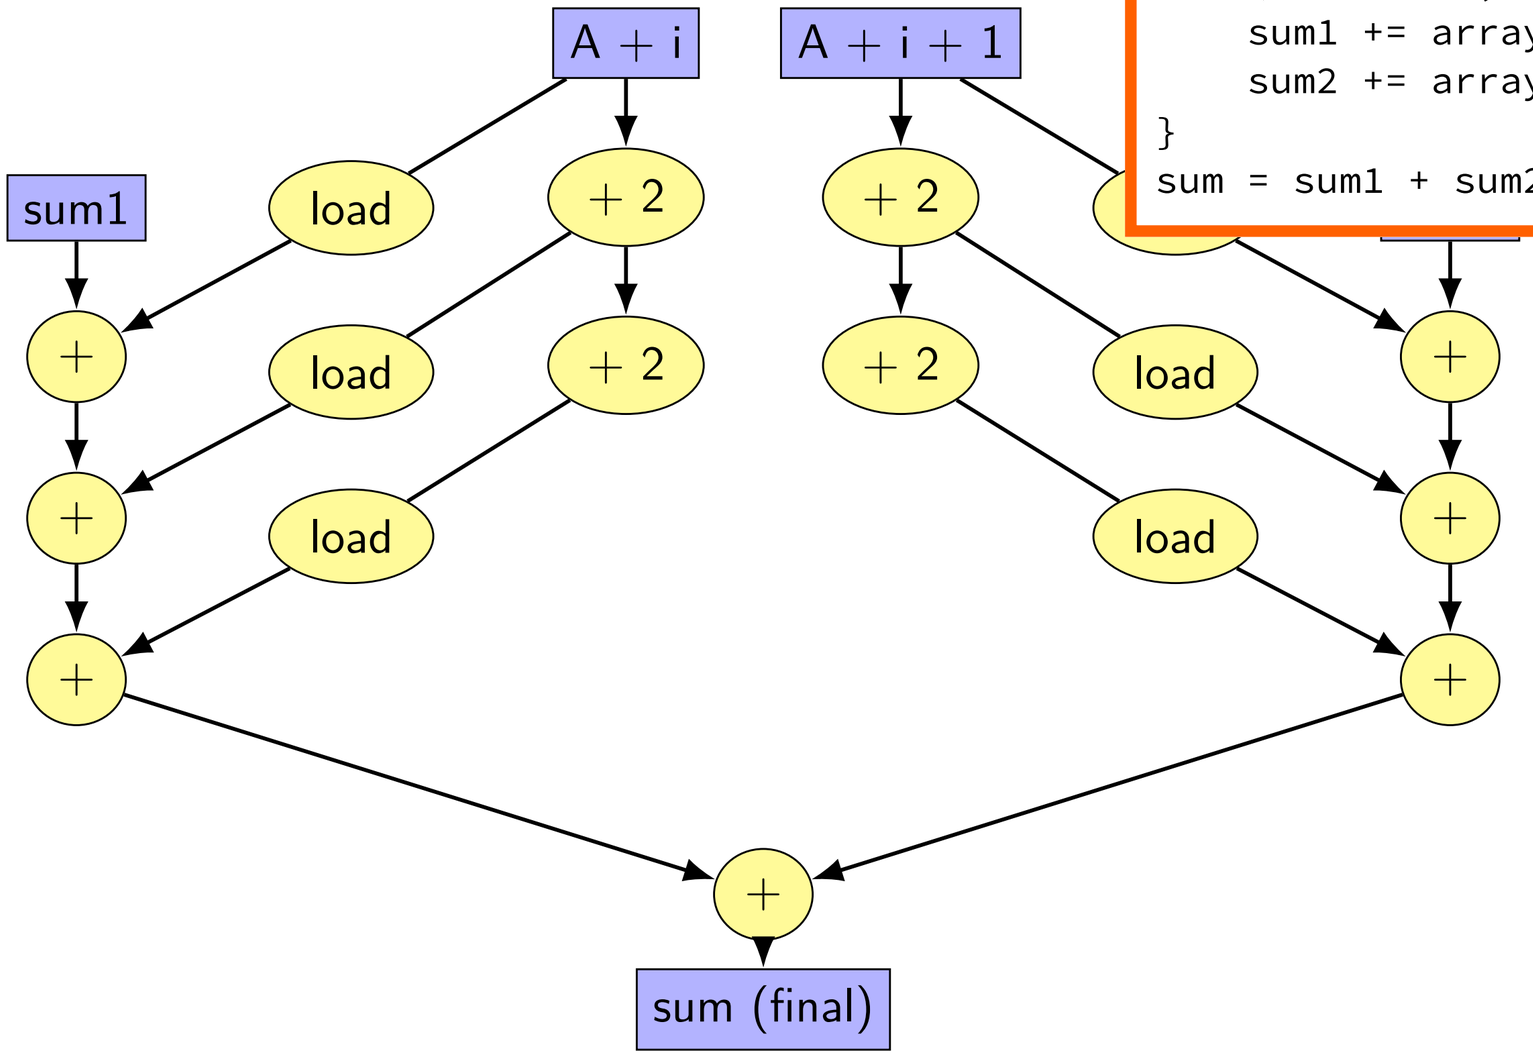
can only do sums one at a time

better data-flow

```
int sum1 = 0, sum2 = 0;
for (int i = 0; i < N; i += 2) {
    sum1 += array[i]
    sum2 += array[i+1]
}
sum = sum1 + sum2;
```

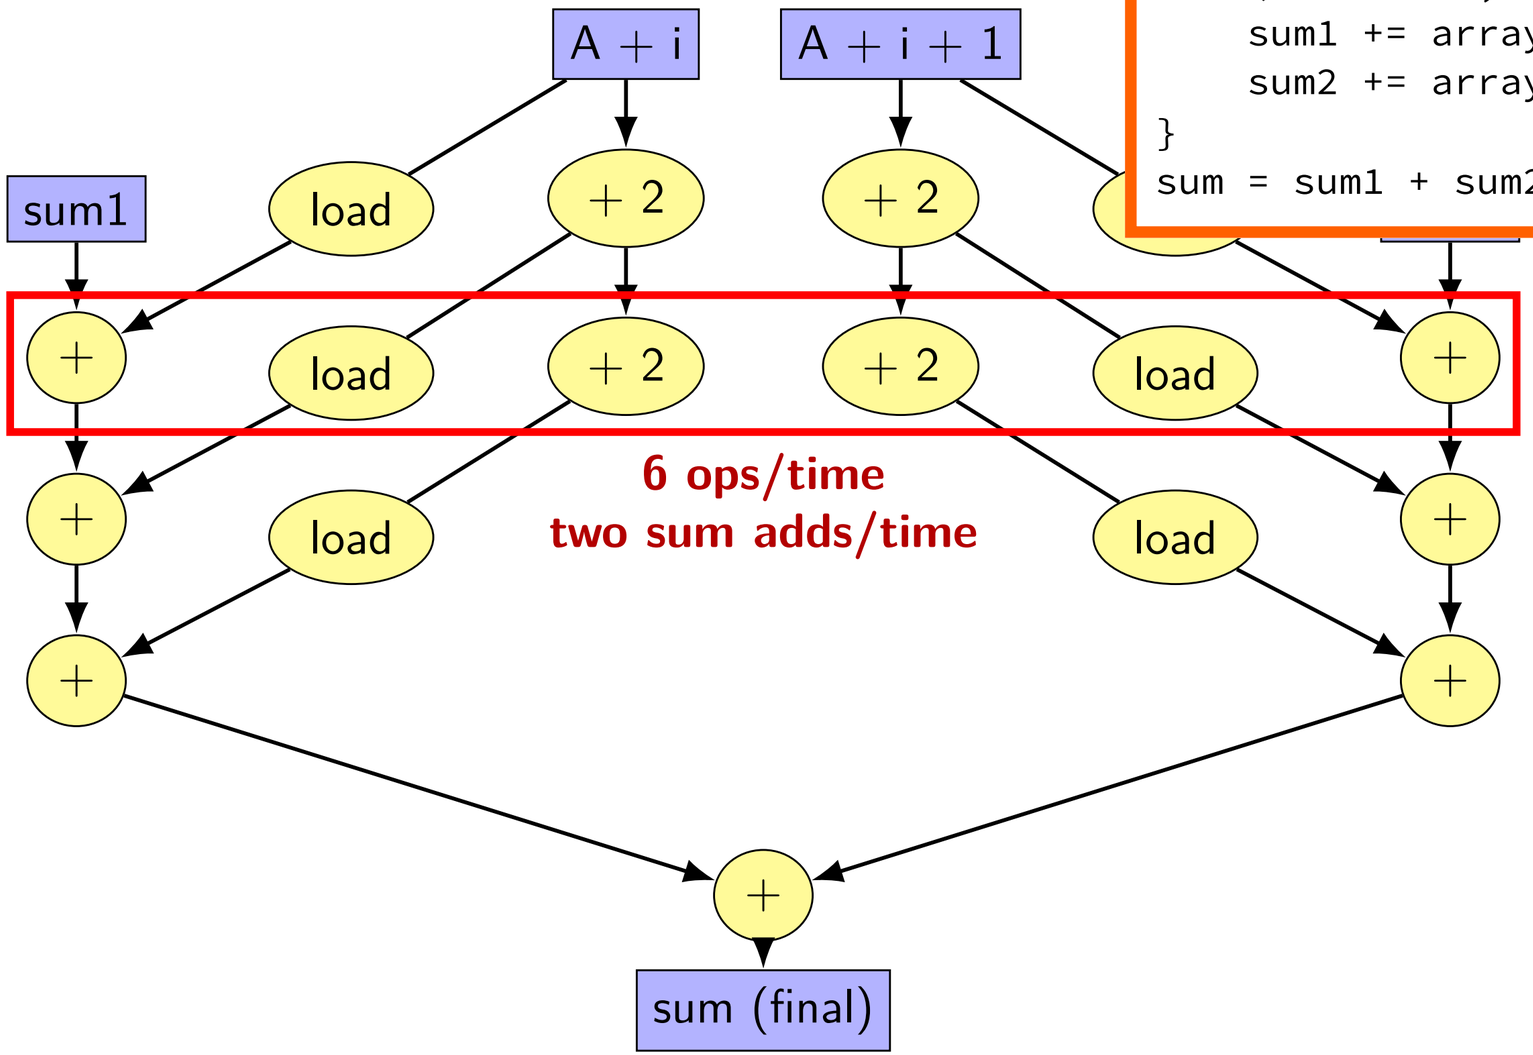
better data-flow

```
int sum1 = 0, sum2 = 0;
for (int i = 0; i < N; i += 2) {
    sum1 += array[i]
    sum2 += array[i+1]
}
sum = sum1 + sum2;
```



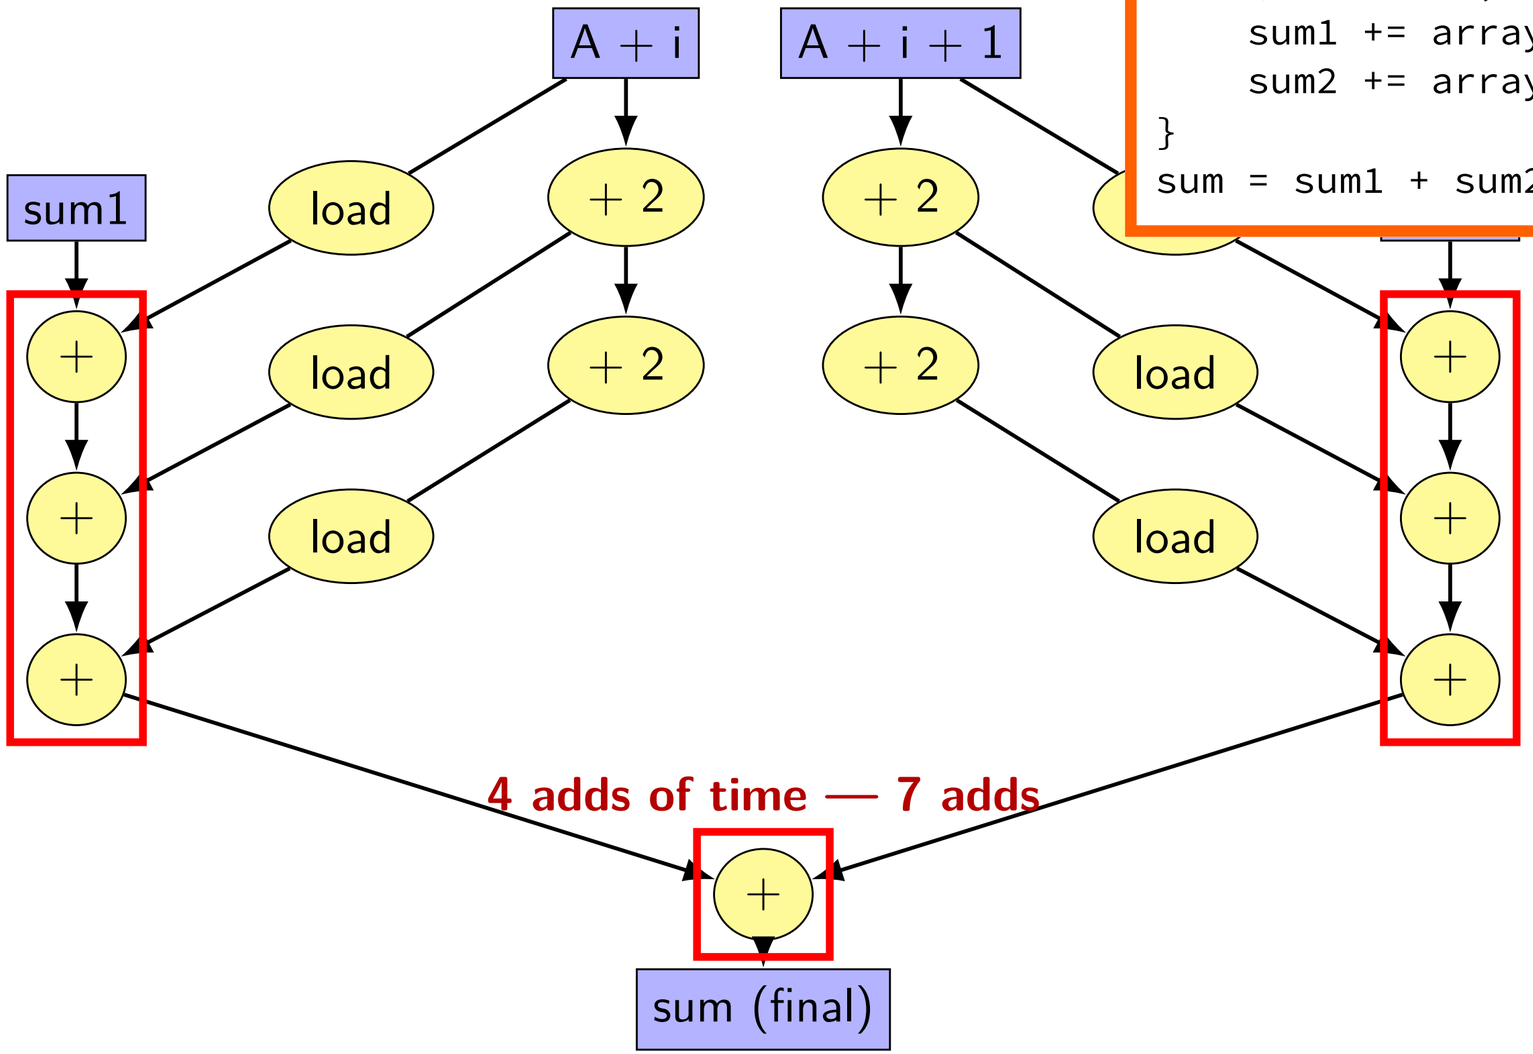
better data-flow

```
int sum1 = 0, sum2 = 0;
for (int i = 0; i < N; i += 2) {
    sum1 += array[i]
    sum2 += array[i+1]
}
sum = sum1 + sum2;
```



better data-flow

```
int sum1 = 0, sum2 = 0;
for (int i = 0; i < N; i += 2) {
    sum1 += array[i]
    sum2 += array[i+1]
}
sum = sum1 + sum2;
```



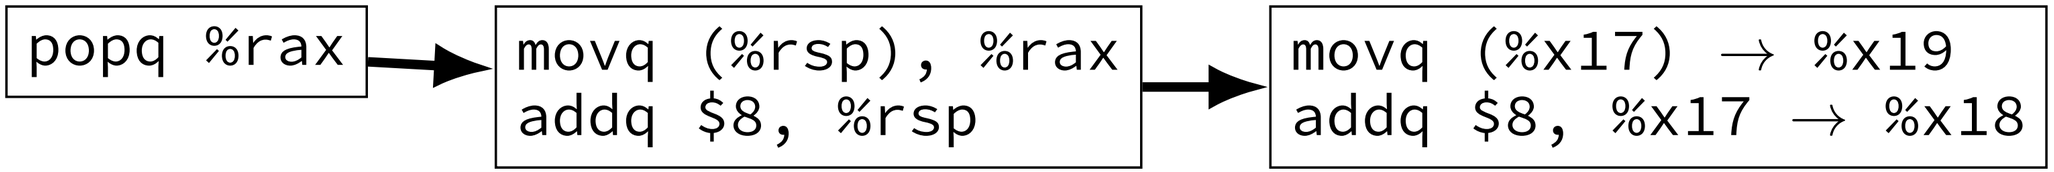
register renaming: missing pieces

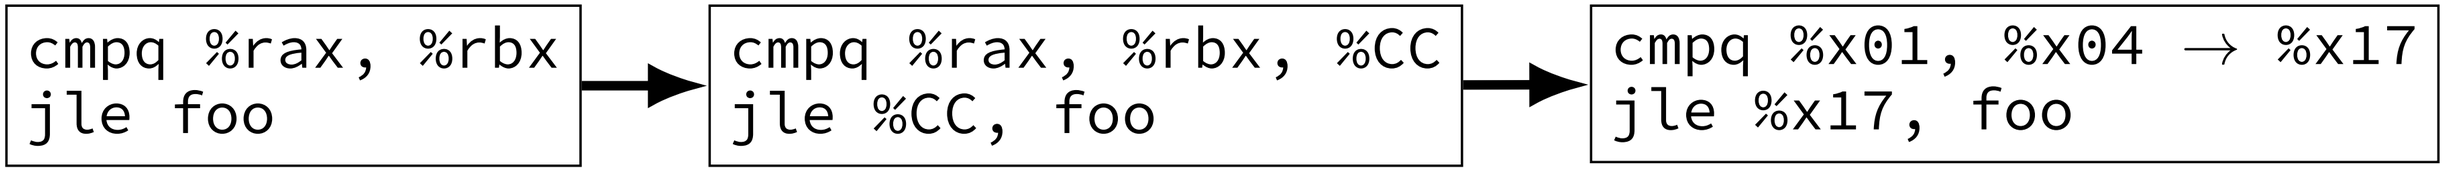
what about "hidden" inputs like `%rsp`, condition codes?

one solution: translate to intructions with additional register parameters

- making %rsp explicit parameter
- turning hidden condition codes into operands!

bonus: can also translate complex instructions to simpler ones

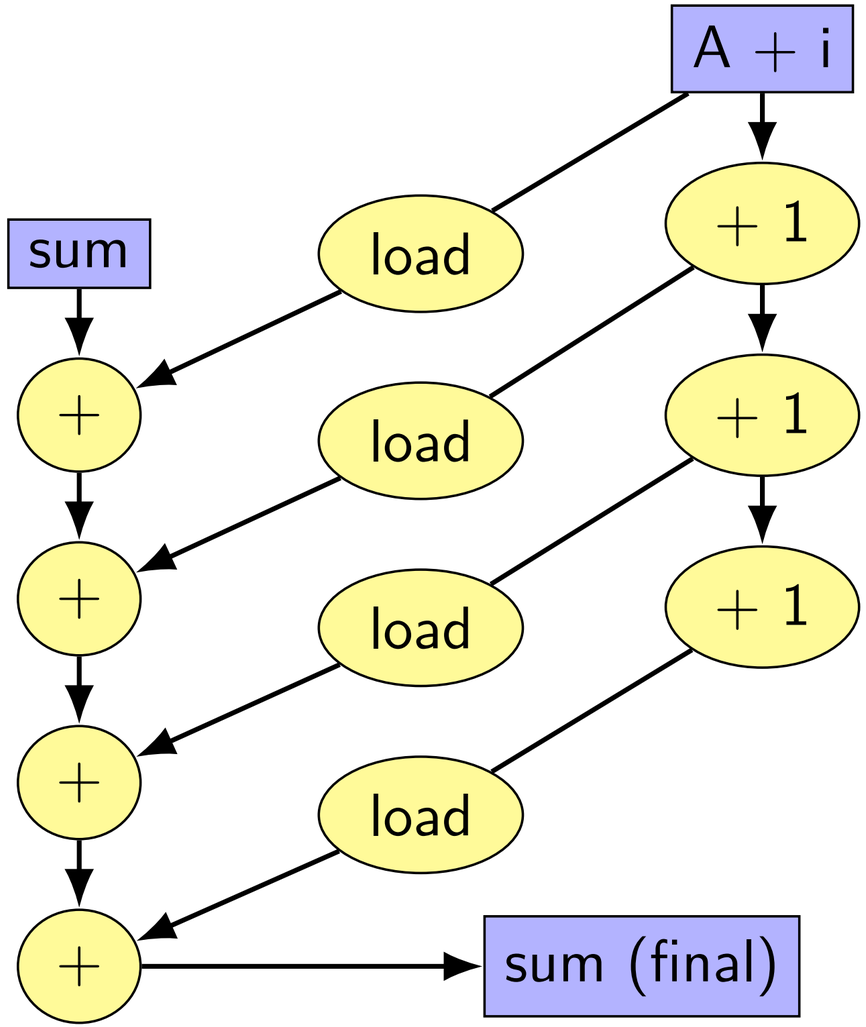




data flow as loop optimization

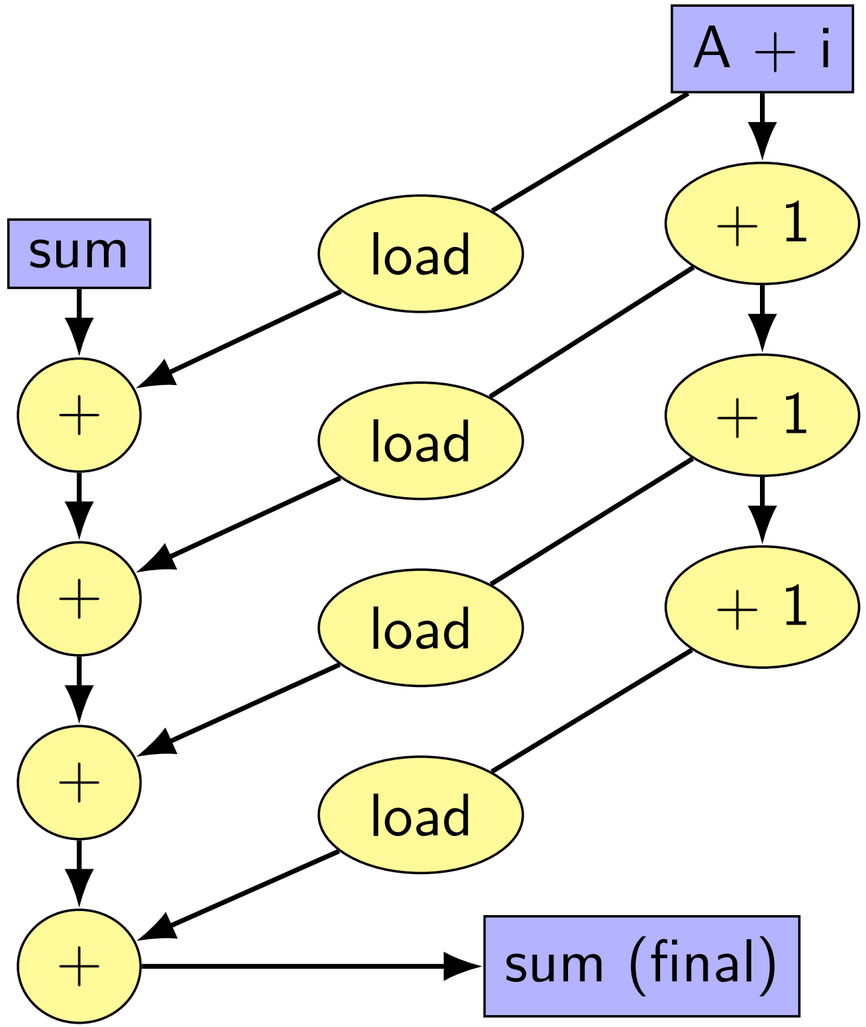
data flow model and limits

data flow model and limits



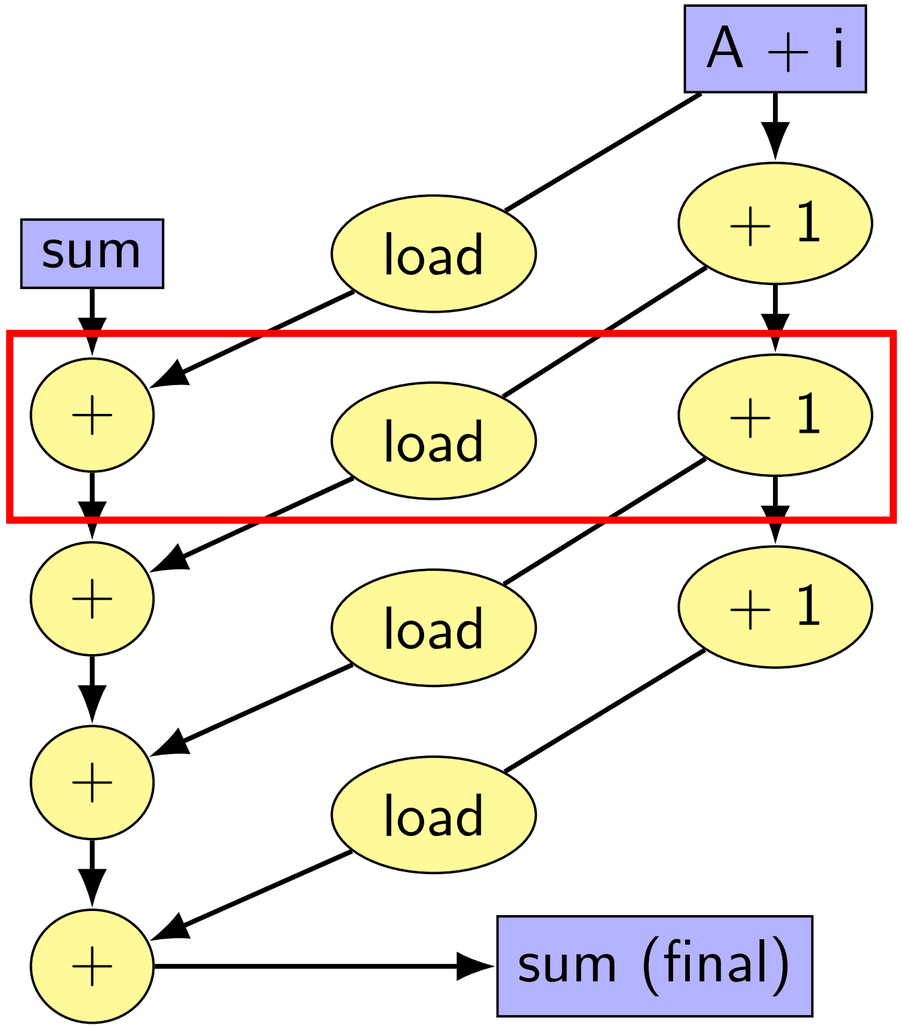
```
for (int i = 0; i < N; i += K) {
        sum += A[i];
        sum += A[i+1];
        …
}
```

data flow model and limits



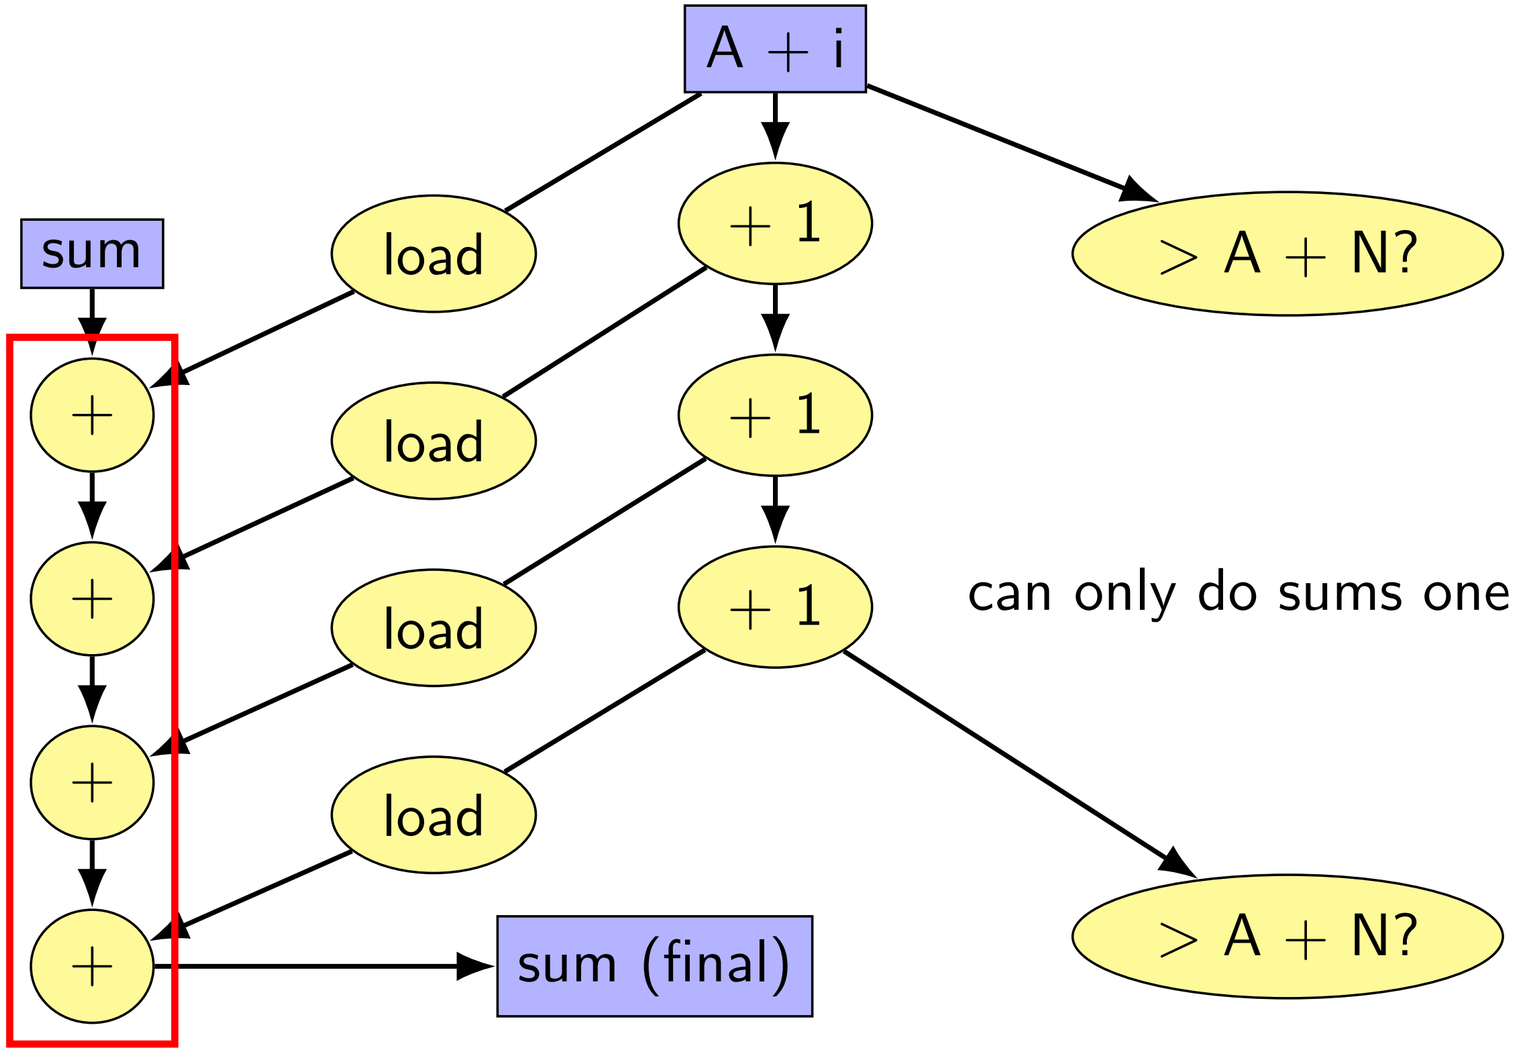
each yellow box = instruction
arrows = dependences
instructions only executed when dependencies ready

data flow model and limits



three ops/cycle (*if* each one cycle)

data flow model and limits



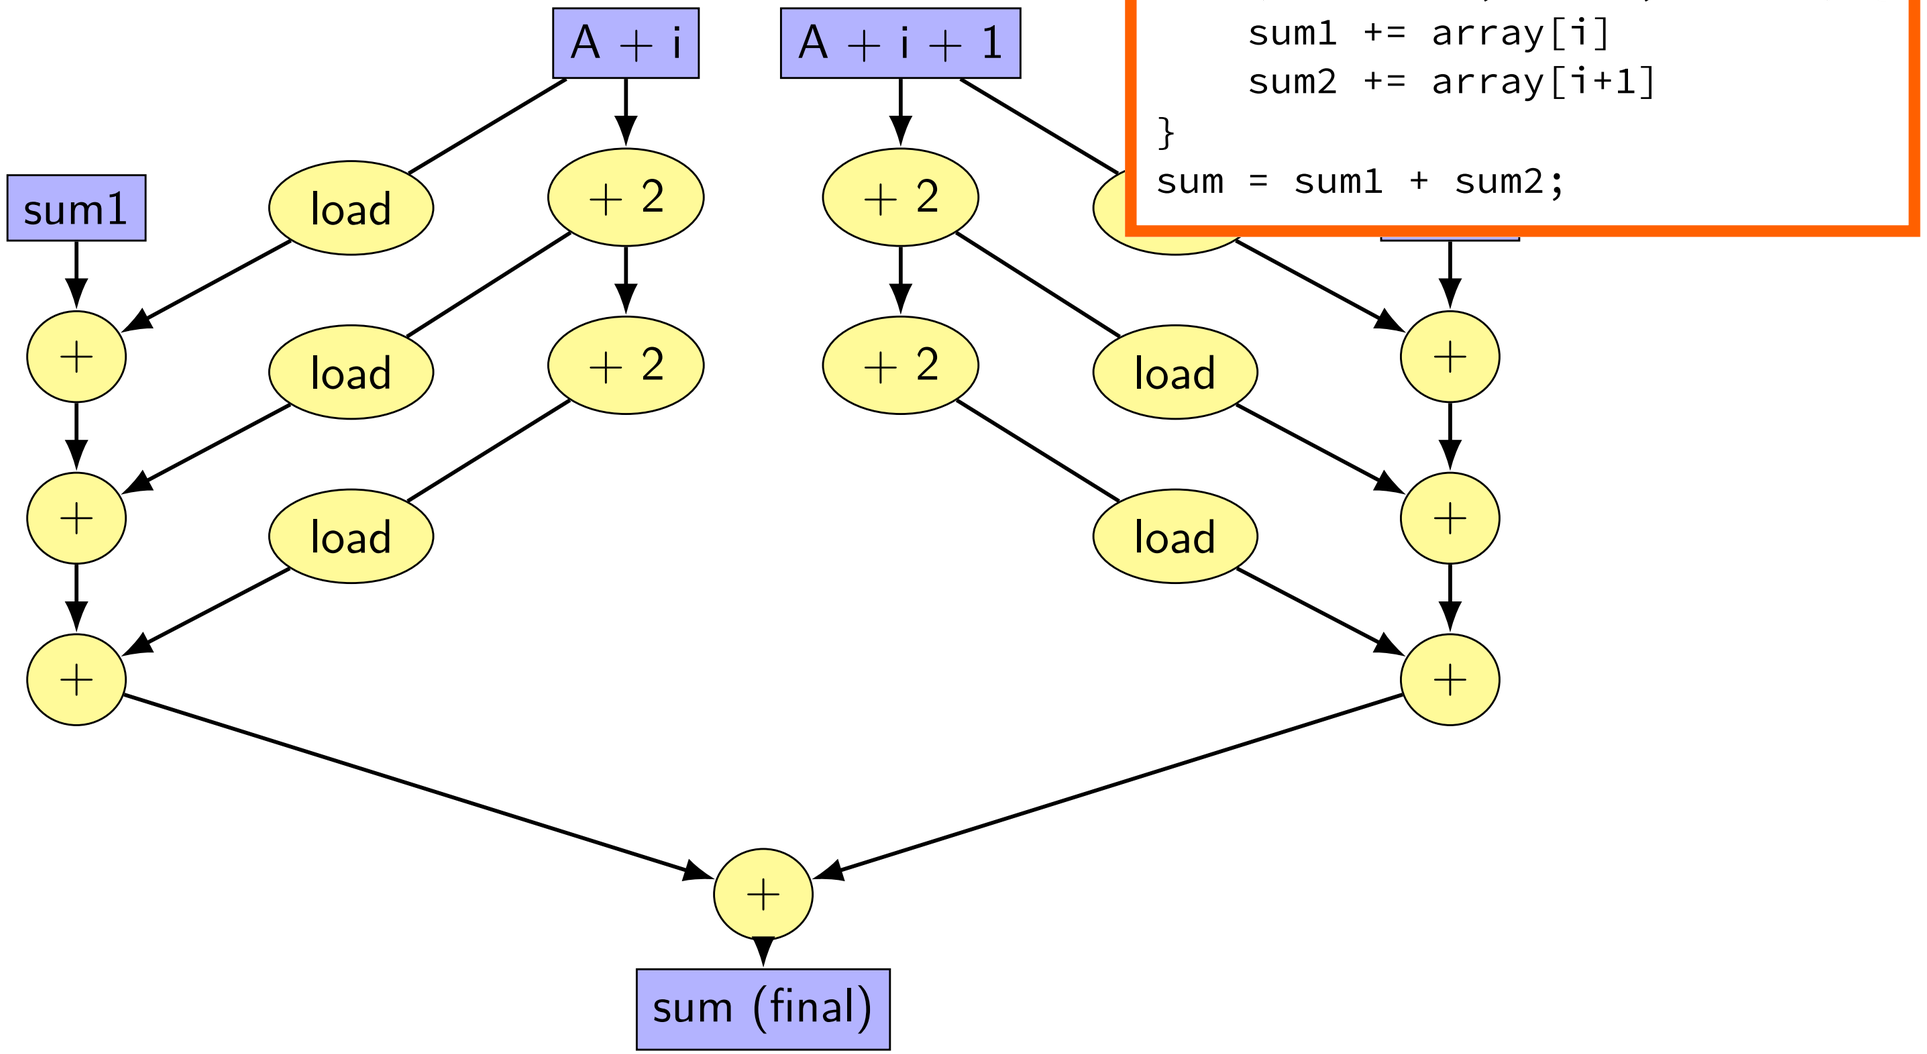
can only do sums one at a time

better data-flow

```
int sum1 = 0, sum2 = 0;
for (int i = 0; i < N; i += 2) {
    sum1 += array[i]
    sum2 += array[i+1]
}
sum = sum1 + sum2;
```

better data-flow

```
int sum1 = 0, sum2 = 0;
for (int i = 0; i < N; i += 2) {
    sum1 += array[i]
    sum2 += array[i+1]
}
sum = sum1 + sum2;
```



better data-flow

```
int sum1 = 0, sum2 = 0;
for (int i = 0; i < N; i += 2) {
    sum1 += array[i]
    sum2 += array[i+1]
}
sum = sum1 + sum2;
```
