# Virtualization

Cache virtualization allows flexible allocation and efficient utilization of cache resources.

# But...what about security?

Cache virtualization enables efficient sharing of the cache.

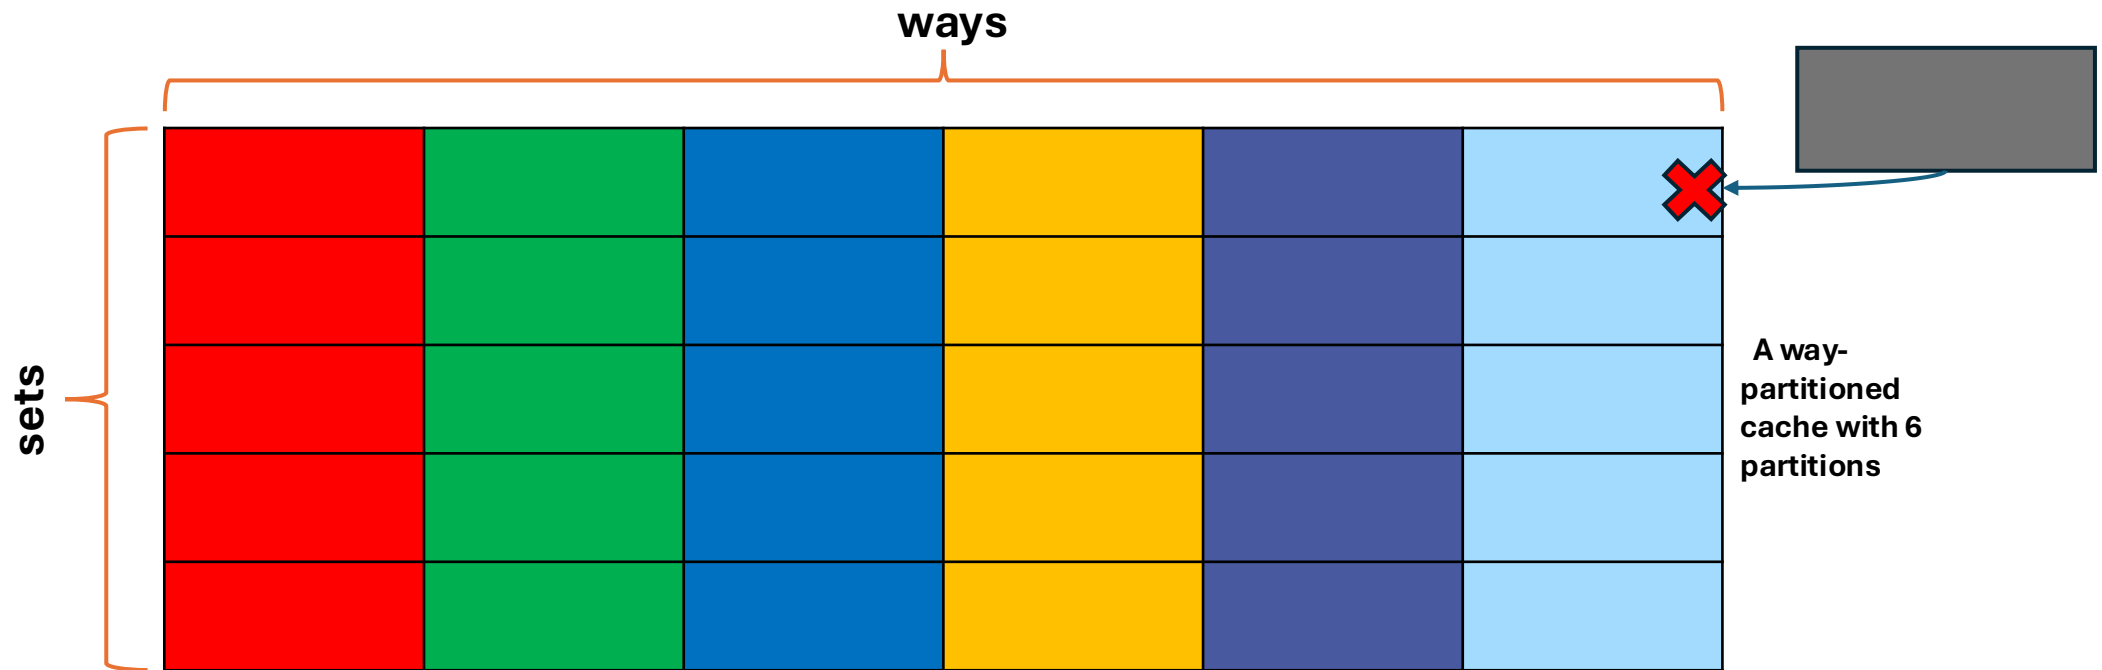

Sharing cache lines  $\Rightarrow$  interference  $\Rightarrow$  information leakage

Solution: partition cache resources by  
cache sets or cache ways.

# Problems with existing secure caches

Existing partitioned caches are not **scalable**.

Number of cache partitions is limited by the number of ways or number of sets in the cache.

# Problems with existing secure caches

Existing partitioned caches lead to **low utilization**.

The variability of cache demand in applications will lead to poor utilization of partitions in a cache.

# Problems with existing secure caches

Existing partitioned caches cannot protect against **indirect** attacks like **confused-deputy**.

The attacker deputizes trusted system entities to bypass existing isolation strategies in the cache.

# Capabilities?

Capability = object name + user's permitted privileges.

Capabilities are **unforgeable** until they are **explicitly revoked**.

Capabilities can also be **shared** between users through **mutual agreement**.

# Ceviche: A capability-based solution

Least-Privilege Access: The capability enforces **a least privileged access** to an authorized object, i.e. cache line.

# Ceviche: A capability-based solution

Unforgeability: Access rights baked into a capability cannot be changed once it is burned.

# Ceviche: A capability-based solution

Intentionality: All cache operations need to be **explicitly enforced/permited** by the capability.

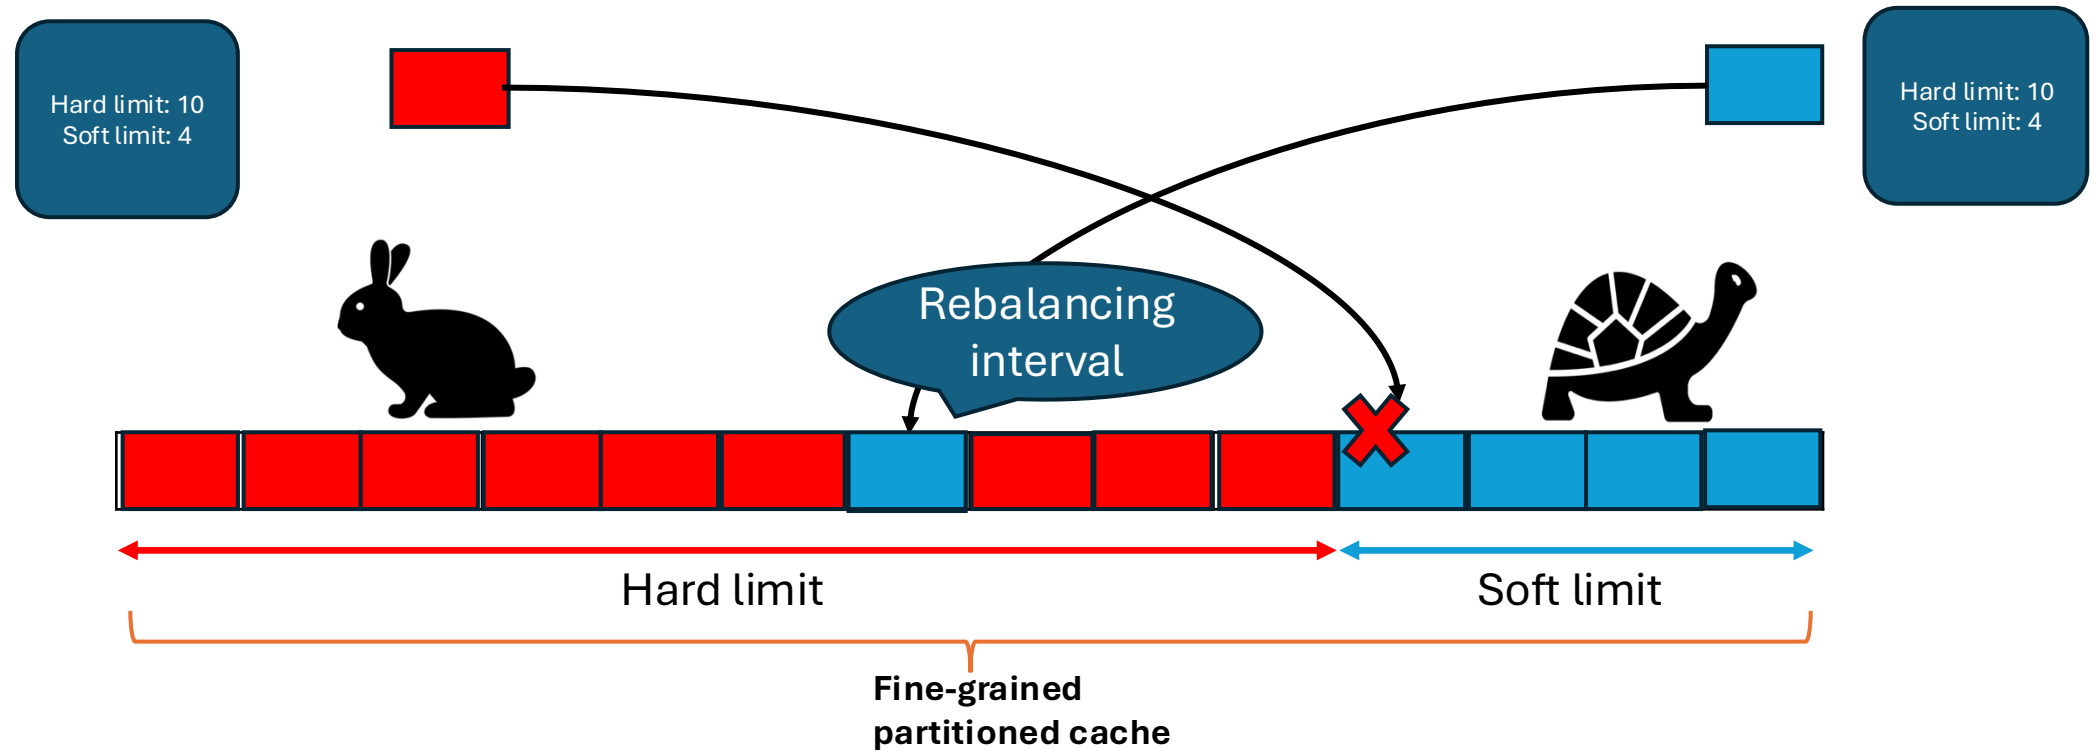

# Ceviche: A capability-based solution

Address Independence: Capabilities break the **tight coupling** between the **virtual/physical address** and the actual **physical location** of the cache line in the cache.

# Ceviche: A capability-based solution

Fairness and Availability: Fairness and availability is ensured through the enforcement of **hard and soft limits**.

# Ceviche: Preventing Confused-Deputy

The trusted entity intentionally uses the attacker's capability, which prevents bypassing existing security

# Results: Single-Threaded Performance

Ceviche incurs a 1.8% performance drop against state-of-the-art caches while providing protection across all cache levels and a wider variety of attacks.

# Results: Multi-Threaded Utilization

With higher number of cores (4, 8, 12), a statically partitioned cache has a lower utilization of the LLC.

# Conclusion

Ceviche is a **novel secure virtualization** solution that protects against a wide variety of attacks.

Ceviche ensures conflict-averse **fully-associative allocation** and fast **direct-mapped lookup**.

Ceviche can **gracefully scale** to multiple domains and larger caches, at modest performance degradation.
