

last time (1)

reader/writer locks

- one writer at time (same as normal locks)

- but multiple readers can 'share' lock

- decision: reader/writer priority

- implementation with monitor (track # readers/writers/waiting)

last time (2)

deadlock requirements and prevention:

mutual exclusion

prevent if unlimited resources/no sharing

hold and wait

prevent if acquire resources all at once, or giving up if can't get resource

no preemption of resources

prevent if can rollback other thread(s) to free up resource

circular wait

prevent if consistent order of resource acquisition

deadlock prevention techniques

infinite resources

or at least enough that never run out

no *mutual exclusion*

no shared resources

no *mutual exclusion*

no waiting

“busy signal” — abort and (maybe) retry
revoke/preempt resources

no *hold and wait /
preemption*

acquire resources in **consistent order**

no *circular wait*

request **all resources at once**

no *hold and wait*

deadlock prevention techniques

infinite resources

or at least enough that never run out

no *mutual exclusion*

no shared resources

no *mutual exclusion*

no waiting

“busy signal” — abort and (maybe) retry
revoke/preempt resources

no *hold and wait /
preemption*

acquire resources in **consistent order**

no *circular wait*

request **all resources at once**

no *hold and wait*

deadlock prevention techniques

infinite resources

or at least enough that never run out

no *mutual exclusion*

no shared resources

no *mutual exclusion*

no waiting

“busy signal” — abort and (maybe) retry
revoke/preempt resources

no *hold and wait /
preemption*

acquire resources in **consistent order**

no *circular wait*

request **all resources at once**

no *hold and wait*

deadlock prevention techniques

infinite resources

or at least enough that never run out

no mutual exclusion

memory allocation: malloc() fails rather than waiting (no deadlock)

locks: pthread_mutex_trylock fails rather than waiting

...

exclusion

no waiting

“busy signal” — abort and (maybe) retry

revoke/preempt resources

*no hold and wait/
preemption*

acquire resources in **consistent order**

no circular wait

request **all resources at once**

no hold and wait

deadlock prevention techniques

infinite resources

or at least enough that never run out

no mutual exclusion

no shared resources

no mutual exclusion

requires some way to undo partial changes to avoid errors
common approach for databases

no waiting

...

“busy signal” — abort and (maybe) retry

*no hold and wait /
preemption*

revoke/preempt resources

acquire resources in **consistent order**

no circular wait

request **all resources at once**

no hold and wait

deadlock prevention techniques

infinite resources

or at least enough that never run out

no *mutual exclusion*

no shared resources

no *mutual exclusion*

no waiting

“busy signal” — abort and (maybe) retry
revoke/preempt resources

no *hold and wait /
preemption*

acquire resources in **consistent order**

no *circular wait*

request **all resources at once**

no *hold and wait*

acquiring locks in consistent order (1)

```
MoveFile(Dir* from_dir, Dir* to_dir, string filename) {  
    if (from_dir->path < to_dir->path) {  
        lock(&from_dir->lock);  
        lock(&to_dir->lock);  
    } else {  
        lock(&to_dir->lock);  
        lock(&from_dir->lock);  
    }  
    ...  
}
```

acquiring locks in consistent order (1)

```
MoveFile(Dir* from_dir, Dir* to_dir, string filename) {  
    if (from_dir->path < to_dir->path) {  
        lock(&from_dir->lock);  
        lock(&to_dir->lock);  
    } else {  
        lock(&to_dir->lock);  
        lock(&from_dir->lock);  
    }  
    ...  
}
```

any ordering will do
e.g. compare pointers

acquiring locks in consistent order (2)

often by convention, e.g. Linux kernel comments:

```
/*
 * ...
 * Lock order:
 *     contex.ldt_usr_sem
 *     mmap_sem
 *     context.lock
 */
```

```
/*
 * ...
 * Lock order:
 *     1. slab_mutex (Global Mutex)
 *     2. node->list_lock
 *     3. slab_lock(page) (Only on some arches and for debugging)
 * ...
 */
```

deadlock prevention techniques

infinite resources

or at least enough that never run out

no *mutual exclusion*

no shared resources

no *mutual exclusion*

no waiting

“busy signal” — abort and (maybe) retry
revoke/preempt resources

no *hold and wait /
preemption*

acquire resources in **consistent order**

no *circular wait*

request **all resources at once**

no *hold and wait*

a prereq note

in CS 3330 or CoA 2, we cover virtual memory for several days

CS3330 = Computer Architecture

CoA2 = Computer Organization and Architecture 2 in the CS 2020 curriculum pilot

for CpEs: the prereq for this class is ECE's *embedded* class

(and *not the CpE architecture class*)

I think little virtual memory coverage in CpE embedded *or* architecture?

don't have precise information about that

address translation

toy program memory

toy program memory

toy program memory

divide memory into **pages** (2^8 bytes in this case)
“virtual” = addresses the program sees

toy program memory

page number is upper bits of address
(because page size is power of two)

toy program memory

rest of address is called **page offset**

toy physical memory

program memory
virtual addresses

11 0000 0000 to 11 1111 1111

2^{20} entries???
way too big!

trigger exception if 0?

0x78849 348

to cache

storing huge page table?

- keep it in memory

 - add special cache for page table entries to handle memory being slow
 - special cached called translation lookaside buffer (TLB)

- use a tree and don't store most invalid page table entries

 - take advantage of large contiguous invalid regions

 - (between stack and heap, most high memory addresses, etc.)

two-level page table naming

what the page table base register points to:

first-level page table

top-level page table

page directory (Intel's term, used in xv6 code)

what first-level page table entries point to

second-level page table

page table (Intel's term, used in xv6 code)

I'll avoid using this term unqualified...

but Intel manuals/xv6 do not

32-bit x86 paging

4096 ($= 2^{12}$) byte pages

4-byte page table entries — stored in memory

two-level table:

- first 10 bits lookup in first level (“page directory”)

- second 10 bits lookup in second level

remaining 12 bits: which byte of 4096 in page?

32-bit x86 paging (in xv6)

xv6 header: mmu.h

// A virtual address 'va' has a three-part structure as follows:

//

<i>// +-----10-----+</i>	<i><i>// +-----10-----+</i></i>	<i><i>// +-----12-----+</i></i>
<i>// Page Directory </i>	<i><i>// Page Table </i></i>	<i><i>// Offset within Page </i></i>
<i>// Index </i>	<i><i>// Index </i></i>	<i><i>// </i></i>
<i>// +-----+</i>	<i><i>// +-----+</i></i>	<i><i>// +-----+</i></i>

// \--- PDX(va) --/ \--- PTX(va) --/

// page directory index

#define PDX(va) (((uint)(va) >> PDXSHIFT) & 0x3FF)

// page table index

#define PTX(va) (((uint)(va) >> PTXSHIFT) & 0x3FF)

// construct virtual address from indexes and offset

#define PGADDR(d, t, o) ((uint)((d) << PDXSHIFT | (t) << PTXSHIFT |

another view

exercise (1)

4096 ($= 2^{12}$) byte pages

4-byte page table entries — stored in memory

two-level table:

- first 10 bits lookup in first level (“page directory”)

- second 10 bits lookup in second level

exercise:

- virtual address 0x12345678

- base pointer 0x1000 (byte address)

- first-level PTE *contents*: PPN 0x14; second-level PTE: PPN 0x15

address of 1st-level PTE? of second-level PTE?

exercise (2)

4096 ($= 2^{12}$) byte pages

4-byte page table entries — stored in memory

two-level table:

- first 10 bits lookup in first level (“page directory”)

- second 10 bits lookup in second level

exercise: how big is...

- a process's x86-32 page tables with 1 valid 4K page?

- a process's x86-32 page tables with all 4K pages populated?

exercise (2)

4096 ($= 2^{12}$) byte pages

4-byte page table entries — stored in memory

two-level table:

- first 10 bits lookup in first level (“page directory”)

- second 10 bits lookup in second level

exercise: how big is...

- a process's x86-32 page tables with 1 valid 4K page? 2 pages (1 first-level, 1 second)

- a process's x86-32 page tables with all 4K pages populated?

exercise (2)

4096 ($= 2^{12}$) byte pages

4-byte page table entries — stored in memory

two-level table:

- first 10 bits lookup in first level (“page directory”)

- second 10 bits lookup in second level

exercise: how big is...

- a process's x86-32 page tables with 1 valid 4K page? 2 pages (1 first-level, 1 second)

- a process's x86-32 page tables with all 4K pages populated? 1025 pages (1 first-level, 1024 second)

xv6 memory layout

xv6 memory layout

xv6 memory layout

xv6 memory layout

xv6 memory layout

xv6 kernel memory

virtual memory $>$ KERNBASE ($0 \times 8000\ 0000$) is for kernel

always mapped as kernel-mode only

protection fault for user-mode programs to access

physical memory address 0 is mapped to $\text{KERNBASE} + 0$

physical memory address N is mapped to $\text{KERNBASE} + N$

not done by hardware — just page table entries OS sets up on boot
very convenient for manipulating page tables with physical addresses

kernel code loaded into contiguous physical addresses

why two mappings?

program memory: layout programs expect
sized based on executable, heap allocations
uses any available memory

kernel code: access to all memory

kernel code: easy translation of physical to virtual addresses
e.g. page table setup: want to use particular physical addresses
no x86 instruction to read/write value using physical address only

xv6 program memory

guard page

1 page after stack

at lower addresses since stack grows towards lower addresses

marked as kernel-mode-only

idea: stack overflow → protection fault → kills program

xv6 types for paging (1)

virtual addresses: pointers (`void*`, etc.)

physical addresses: ints

P2V/V2P

V2P(x) (virtual to physical)

convert *kernel* address x to physical address

subtract KERNBASE (0x8000 0000)

assumes you pass a kernel address

have user address? need full page table lookup instead

P2V(x) (physical to virtual)

convert *physical* address x to kernel address

add KERNBASE (0x8000 0000)

xv6 convention: virtual addresses represented using pointers

xv6 convention: physical addresses represented using integers

P2V/V2P

V2P(x) (virtual to physical)

convert *kernel* address x to physical address

subtract KERNBASE (0x8000 0000)

assumes you pass a kernel address

have user address? need full page table lookup instead

P2V(x) (physical to virtual)

convert *physical* address x to kernel address

add KERNBASE (0x8000 0000)

xv6 convention: virtual addresses represented using pointers

xv6 convention: physical addresses represented using integers

P2V/V2P

Figure 4-4. Formats of CR3 and Paging-Structure Entries with 32-Bit Paging

x86-32 page table entry v addresses

trick: page table entry with lower bits zeroed =
 physical *byte* address of corresponding page
 page # is address of page (2^{12} byte units)

makes constructing page table entries simpler:
 physicalAddress | flagsBits

x86-32 pagetables: page table entries

xv6 header: mmu.h

```
// Page table/directory entry flags.
#define PTE_P           0x001    // Present

}
```

xv6: manually setting page table entry

```
pde_t *some_page_table; // if top-level table
pte_t *some_page_table; // if next-level table
...
...
some_page_table[index] =
    PTE_P | PTE_W | PTE_U | base_physical_address;
/* P = present; W = writable; U = user-mode accessible */
```

xv6 page table-related functions

`kalloc/kfree` — allocate physical page, return kernel address

`walkpgdir` — get pointer to second-level page table entry
...to check it/make it valid/invalid/point somewhere/etc.

`mappages` — set range of page table entries
implementation: loop using `walkpgdir`

`allocvm` — create new set of page tables, set kernel (high) part
entries for `0x8000 0000` and up set
allocate new first-level table plus several second-level tables

`allocvm` — allocate new user memory
setup user-accessible memory
allocate new second-level tables as needed

`deallocvm` — deallocate user memory

skipping the guard page

```
void example() {  
    int array[2000];  
    array[0] = 1000;  
    ...  
}
```

example:

```
    subl    $8024, %esp // allocate 8024 bytes on stack  
    movl    $1000, 12(%esp) // write near bottom of allocation  
                                // goes beyond guard page  
                                // since not all of array init'd  
    ....
```
