

CS4102 Algorithms  
Spring 2019

**Warm up**

Given access to unlimited quantities of pennies, nickels, dimes, and quarters, (worth value 1, 5, 10, 25 respectively), provide an algorithm which gives change for a given value  $x$  using the fewest number of coins.

---

---

---

---

---

---

---

---

**Change Making**

43 cents

---

---

---

---

---

---

---

---

**Change Making Algorithm**

- Given: target value  $x$ , list of coins  $C = [c_1, \dots, c_n]$  (in this case  $C = [1,5,10,25]$ )
- Repeatedly select the largest coin less than the remaining target value:

```
while( $x > 0$ )
  let  $c = \max\{c_i \in \{c_1, \dots, c_n\} \mid c_i \leq x\}$ 
  print  $c$ 
   $x = x - c$ 
```

---

---

---

---

---

---

---

---

### Why does this always work?

- If  $x < 5$ , then pennies only
  - 5 pennies can be exchanged for a nickel  
Only case Greedy uses pennies!
- If  $5 \leq x < 10$  we must have a nickel
  - 2 nickels can be exchanged for a dime  
Only case Greedy uses nickels!
- If  $10 \leq x < 25$  we must have at least 1 dime
  - 3 dimes can be exchanged for a quarter and a nickel  
Only case Greedy uses dimes!
- If  $x \geq 25$  we must have at least 1 quarter  
Only case Greedy uses quarters!

---

---

---

---

### Today's Keywords

- Dynamic Programming
- Gerrymandering
- Greedy Algorithms
- Choice Function
- Change Making

5

---

---

---

---

---

---

---

---

### CLRS Readings

- Chapter 15
- Chapter 16

6

---

---

---

---

---

---

---

---

## Homeworks

- Homework 5 due Wednesday March 27 at 11pm
  - Seam Carving!
  - Dynamic Programming (implementation)
  - Java or Python
- Homework 6 out tonight, due Wednesday April 3 at 11pm
  - Dynamic Programming and Greedy Algorithms
  - Written (using Latex!)

7

---

---

---

---

---

---

---

---

## Dynamic Programming

- Requires **Optimal Substructure**
  - Solution to larger problem contains the solutions to smaller ones
- Idea:
  1. Identify recursive structure of the problem
    - What is the “last thing” done?
  2. Select a good order for solving subproblems
    - “Top Down”: Solve each recursively
    - “Bottom Up”: Iteratively solve smallest to largest
  3. Save solution to each subproblem in memory

8

---

---

---

---

---

---

---

---

## Generic Top-Down Dynamic Programming Soln

```

mem = {}
def myDPalgo(problem):
    if mem[problem] not blank:
        return mem[problem]
    if baseCase(problem):
        solution = solve(problem)
        mem[problem] = solution
        return solution
    for subproblem of problem:
        subsolutions.append(myDPalgo(subproblem))
    solution = OptimalSubstructure(subsolutions)
    mem[problem] = solution
    return solution

```

9

---

---

---

---

---

---

---

---

### DP Algorithms so far

- $2 \times n$  domino tiling (Fibonacci)
- Log cutting
- Matrix Chaining
- Longest Common Subsequence
- Seam Carving

10

---

---

---

---

---

---

---

---

### Domino Tiling

Tile(n):

```

Initialize Memory M
M[0] = 0
M[1] = 0
for i = 0 to n:
    M[i] = M[i-1] + M[i-2]
return M[n]
    
```

11

---

---

---

---

---

---

---

---

### Log Cutting

Solve Smallest subproblem first

$$Cut(4) = \max \begin{cases} Cut(3) + P[1] \\ Cut(2) + P[2] \\ Cut(1) + P[3] \\ Cut(0) + P[4] \end{cases}$$

12

---

---

---

---

---

---

---

---

### Matrix Chaining

 $M_6$

$$Best(i, j) = \min_{k=1}^{j-1} (Best(i, k) + Best(k+1, j) + r_i r_{k+1} c_j)$$

$$Best(i, i) = 0$$

$Best(1,6) = \min$

0	5375	7875	9375	11875	15125
0	2625	4375	7125	10500	
0	0	750	2500	5375	
0	0	0	1000	3500	
0	0	0	0	5000	
0	0	0	0	0	

$Best(1,6) = \min$ 

- $Best(1,1) + Best(2,6) + r_1 r_2 c_6$
- $Best(1,2) + Best(3,6) + r_1 r_3 c_6$
- $Best(1,3) + Best(4,6) + r_1 r_4 c_6$
- $Best(1,4) + Best(5,6) + r_1 r_5 c_6$
- $Best(1,5) + Best(6,6) + r_1 r_6 c_6$

---

---

---

---

---

---

---

---

### Longest Common Subsequence

$$LCS(i, j) = \begin{cases} 0 & \text{if } i = 0 \text{ or } j = 0 \\ LCS(i-1, j-1) + 1 & \text{if } X[i] = Y[j] \\ \max(LCS(i, j-1), LCS(i-1, j)) & \text{otherwise} \end{cases}$$

$X =$

	0	A	T	C	T	G	A	T
0	0	0	0	0	0	0	0	0
T	0	0	1	1	1	1	1	1
G	0	0	1	1	1	2	2	2
C	0	0	1	2	2	2	2	2
A	0	1	1	2	2	2	3	3
T	0	1	2	2	3	3	3	4
A	0	1	2	2	3	3	4	4

To fill in cell  $(i, j)$  we need cells  $(i-1, j-1)$ ,  $(i-1, j)$ ,  $(i, j-1)$   
 Fill from Top->Bottom, Left->Right (with any preference)

Supreme Court Associate Justice Anthony Kennedy gave no sign that he has abandoned his view that extreme partisan gerrymandering might violate the Constitution. | Eric Thayer/Getty Images

### Supreme Court eyes partisan gerrymandering

Anthony Kennedy is seen as the swing vote that could blunt GOP's map-drawing successes.

---

---

---

---

---

---

---

---

### Gerrymandering

- Manipulating electoral district boundaries to favor one political party over others
- Coined in an 1812 Political cartoon
- Governor Gerry signed a bill that redistricted Massachusetts to benefit his Democratic-Republican Party

---

---

---

---

---

---

---

---

### According to the Supreme Court

- Gerrymandering cannot be used to:
  - Disadvantage racial/ethnic/religious groups
- It can be used to:
  - Disadvantage political parties

---

---

---

---

---

---

---

---

---

---

---

---

---

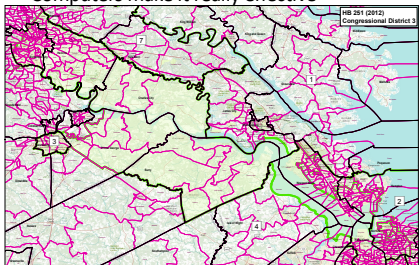

---

---

---

### How does it work?

- States are broken into precincts
- All precincts have the same size
- We know voting preferences of each precinct
- Group precincts into districts to maximize the number of districts won by my party

---

---

---

---

---

---

---

---

### Gerrymandering Problem Statement

- Given:
  - A list of precincts:  $p_1, p_2, \dots, p_n$  — *precincts, n of them*
  - Each containing  $m$  voters
- Output:
  - Districts  $D_1, D_2 \subset \{p_1, p_2, \dots, p_n\}$
  - Where  $|D_1| = |D_2|$
  - $R(D_1), R(D_2) > \frac{mn}{4}$   *$\frac{n}{2} \cdot m \cdot \frac{1}{2}$* 
    - $R(D_i)$  gives number of "Regular Party" voters in  $D_i$
    - $R(D_i) > \frac{mn}{4}$  means  $D_i$  is majority "Regular Party"
  - "failure" if no such solution is possible

---

---

---

---

---

---

---

---

### Dynamic Programming

- Requires **Optimal Substructure**
  - Solution to larger problem contains the solutions to smaller ones
- Idea:
  1. Identify recursive structure of the problem
    - What is the "last thing" done?
  2. Select a good order for solving subproblems
    - "Top Down": Solve each recursively
    - "Bottom Up": Iteratively solve smallest to largest
  3. Save solution to each subproblem in memory

---

---

---

---

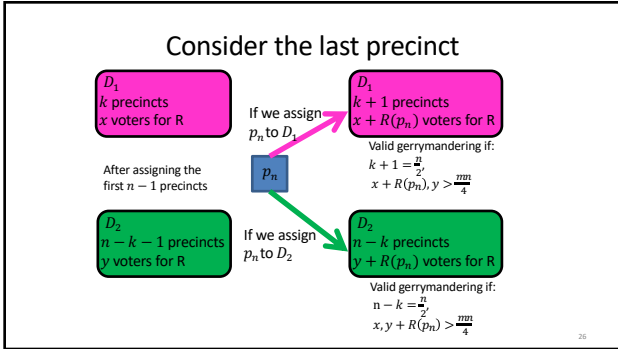

---

---

---

---

---

---

---

---

---

---

---

---

### Define Recursive Structure

$S(j, k, x, y) = \text{True}$  if from among the first  $j$  precincts:  
 $n \times n \times mn \times mn$   $k$  are assigned to  $D_1$   
 exactly  $x$  vote for R in  $D_1$   
 exactly  $y$  vote for R in  $D_2$

**4D Dynamic Programming!!!**

---

---

---

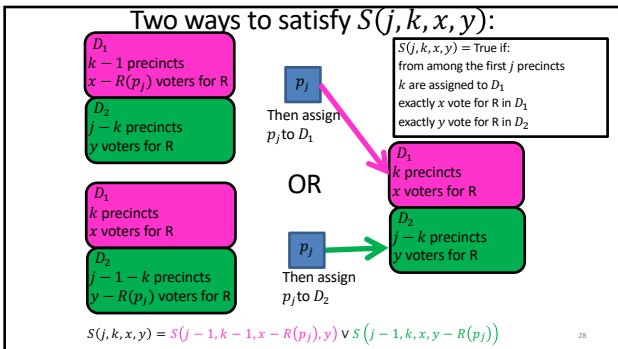

---

---

---

---

---

---

---

---

---

---

---

---

---

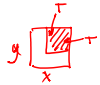

### Final Algorithm

$S(j, k, x, y) = S(j-1, k-1, x-R(p_j), y) \vee S(j-1, k, x, y-R(p_j))$

Initialize  $S(0,0,0,0) = \text{True}$   
 for  $j = 1, \dots, n$ :  
   for  $k = 1, \dots, \min(j, \frac{n}{2})$ :  
     for  $x = 0, \dots, jm$ :  
       for  $y = 0, \dots, jm$ :  
          $S(j, k, x, y) =$   
            $S(j-1, k-1, x-R(p_j), y)$   
            $\vee S(j-1, k, x, y-R(p_j))$

$S(j, k, x, y) = \text{True}$  if:  
 from among the first  $j$  precincts  
 $k$  are assigned to  $D_1$   
 exactly  $x$  vote for R in  $D_1$   
 exactly  $y$  vote for R in  $D_2$

Search for True entry at  $S(n, \frac{n}{2}, \frac{mn}{4}, \frac{mn}{4})$

---

---

---

---

---

---

---

---

### Run Time

$S(j, k, x, y) = S(j-1, k-1, x-R(p_j), y) \vee S(j-1, k, x, y-R(p_j))$

Initialize  $S(0,0,0,0) = \text{True}$   
 $n$  for  $j = 1, \dots, n$ :  
 $\frac{n}{2}$  for  $k = 1, \dots, \min(j, \frac{n}{2})$ :  $\Theta(n^4 m^2)$   
 $nm$  for  $x = 0, \dots, jm$ :  
 $nm$  for  $y = 0, \dots, jm$ :  
    $S(j, k, x, y) =$   
      $S(j-1, k-1, x-R(p_j), y)$   
      $\vee S(j-1, k, x, y-R(p_j))$

Search for True entry at  $S(n, \frac{n}{2}, \frac{mn}{4}, \frac{mn}{4})$

---

---

---

---

---

---

---

---

### $\Theta(n^4 m^2)$

- Runtime depends on the *value* of  $m$ , not *size* of  $m$
- Run time is exponential in size of input
- Note: Gerrymandering is NP-Complete

---

---

---

---

---

---

---

---
