A weakness of hashing

Problem: For any hash function h, a set of keys exists that can cause the average access time of a hash table to skyrocket.

• An adversary can pick all keys from $\{k \in U : h(k) = i\}$ for some slot *i*.

IDEA: Choose the hash function at random, independently of the keys.

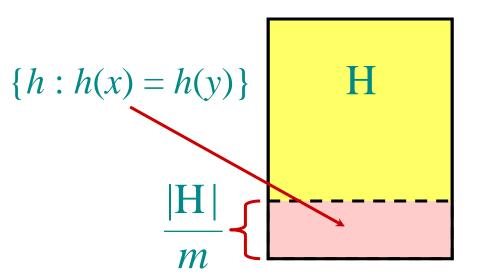

• Even if an adversary can see your code, he or she cannot find a bad set of keys, since he or she doesn't know exactly which hash function will be chosen.

Universal hashing

Definition. Let *U* be a universe of keys, and let H be a finite collection of hash functions, each mapping *U* to $\{0, 1, ..., m-1\}$. We say H is *universal* if for all $x, y \in U$, where $x \neq y$, we have $|\{h \in H : h(x) = h(y)\}| \leq |H|/m$.

That is, the chance of a collision between *x* and *y* is $\leq 1/m$ if we choose *h* randomly from H.

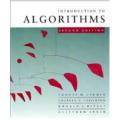

Universality is good

Theorem. Let h be a hash function chosen (uniformly) at random from a universal set H of hash functions. Suppose h is used to hash n arbitrary keys into the m slots of a table T. Then, for a given key x, we have

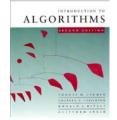

E[#collisions with x] < n/m.

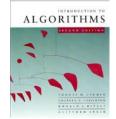

Proof of theorem

Proof. Let C_x be the random variable denoting the total number of collisions of keys in T with x, and let $c_{xy} = \begin{cases} 1 & \text{if } h(x) = h(y), \\ 0 & \text{otherwise.} \end{cases}$

Note:
$$E[c_{xy}] = 1/m$$
 and $C_x = \sum_{y \in T - \{x\}} c_{xy}$.

 $E[C_x] = E \left| \sum_{y \in T - \{x\}} c_{xy} \right|$ • Take expectation of both sides.

 $E[C_x] = E \left| \sum_{y \in T - \{x\}} c_{xy} \right|$ • Take expectation of both sides. $= \sum E[c_{xy}]$ $y \in T - \{x\}$

- Linearity of expectation.

$$E[C_x] = E\left[\sum_{y \in T - \{x\}} c_{xy}\right]$$
$$= \sum_{y \in T - \{x\}} E[c_{xy}]$$
$$= \sum_{y \in T - \{x\}} \frac{1}{m}$$
$$y \in T - \{x\}$$

- Take expectation of both sides.
- Linearity of expectation.
- $E[c_{xy}] = 1/m$.

$$E[C_x] = E\left[\sum_{y \in T - \{x\}} c_{xy}\right]$$
$$= \sum_{y \in T - \{x\}} E[c_{xy}]$$
$$= \sum_{y \in T - \{x\}} \frac{1}{m}$$
$$= \frac{n-1}{m} \cdot \square$$

- Take expectation of both sides.
- Linearity of expectation.
- $E[c_{xy}] = 1/m$.

• Algebra.

ALGORITHMS

Constructing a set of universal hash functions

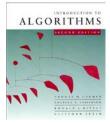

Let *m* be prime. Decompose key *k* into r + 1 digits, each with value in the set $\{0, 1, ..., m-1\}$. That is, let $k = \langle k_0, k_1, ..., k_r \rangle$, where $0 \le k_i < m$.

Randomized strategy:

Pick $a = \langle a_0, a_1, ..., a_r \rangle$ where each a_i is chosen randomly from $\{0, 1, ..., m-1\}$.

Define
$$h_a(k) = \sum_{i=0}^r a_i k_i \mod m$$
. Dot product,
modulo m
How big is $H = \{h_a\}$? $|H| = m^{r+1}$. $\leftarrow \frac{\text{REMEMBER}}{\text{THIS!}}$

Universality of dot-product hash functions

Theorem. The set $H = \{h_a\}$ is universal.

Proof. Suppose that $x = \langle x_0, x_1, \dots, x_r \rangle$ and y = $\langle y_0, y_1, \dots, y_r \rangle$ be distinct keys. Thus, they differ in at least one digit position, wlog position 0. For how many $h_a \in H$ do x and y collide?

We must have $h_a(x) = h_a(y)$, which implies that

$$\sum_{i=0}^{r} a_i x_i \equiv \sum_{i=0}^{r} a_i y_i \pmod{m}.$$

Equivalently, we have

$$\sum_{i=0}^{r} a_i (x_i - y_i) \equiv 0 \pmod{m}$$

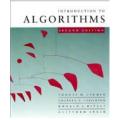

or

$$a_0(x_0 - y_0) + \sum_{i=1}^r a_i(x_i - y_i) \equiv 0 \pmod{m}$$
,

which implies that

$$a_0(x_0 - y_0) \equiv -\sum_{i=1}^r a_i(x_i - y_i) \pmod{m}$$

٠

Fact from number theory

Theorem. Let *m* be prime. For any $z \in Z_m$ such that $z \neq 0$, there exists a unique $z^{-1} \in Z_m$ such that

 $z \cdot z^{-1} \equiv 1 \pmod{m}.$

Example: m = 7.

z123456
$$z^{-1}$$
145236

Back to the proof

We have

$$a_0(x_0 - y_0) \equiv -\sum_{i=1}^r a_i(x_i - y_i) \pmod{m},$$

and since $x_0 \neq y_0$, an inverse $(x_0 - y_0)^{-1}$ must exist, which implies that

$$a_0 \equiv \left(-\sum_{i=1}^r a_i (x_i - y_i)\right) \cdot (x_0 - y_0)^{-1} \pmod{m}.$$

Thus, for any choices of $a_1, a_2, ..., a_r$, exactly one choice of a_0 causes x and y to collide.

October 5, 2005 Copyright © 2001-5 by Erik D. Demaine and Charles E. Leiserson L7.14

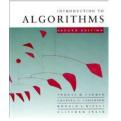

Proof (completed)

- *Q*. How many h_a 's cause x and y to collide?
- A. There are *m* choices for each of $a_1, a_2, ..., a_r$, but once these are chosen, exactly one choice for a_0 causes *x* and *y* to collide, namely

$$a_0 = \left(\left(-\sum_{i=1}^r a_i (x_i - y_i) \right) \cdot (x_0 - y_0)^{-1} \right) \mod m.$$

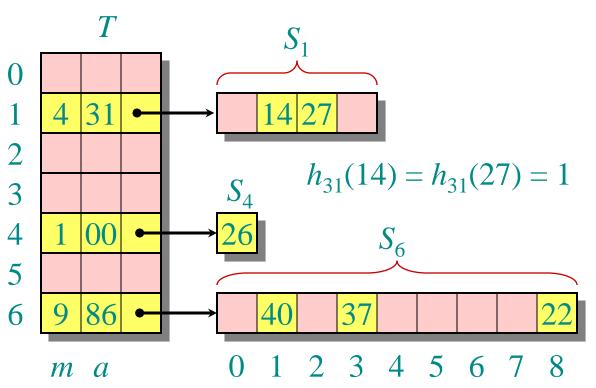

Thus, the number of h_a 's that cause x and y to collide is $m^r \cdot 1 = m^r = |\mathsf{H}|/m$.

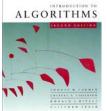

Perfect hashing

Given a set of *n* keys, construct a static hash table of size m = O(n) such that SEARCH takes $\Theta(1)$ time in the *worst case*.

IDEA: Twolevel scheme with universal hashing at both levels. *No collisions at level 2!*

Collisions at level 2

Theorem. Let H be a class of universal hash functions for a table of size $m = n^2$. Then, if we use a random $h \in H$ to hash *n* keys into the table, the expected number of collisions is at most 1/2. *Proof.* By the definition of universality, the probability that 2 given keys in the table collide under h is $1/m = 1/n^2$. Since there are $\binom{n}{2}$ pairs of keys that can possibly collide, the expected number of collisions is

$$\binom{n}{2} \cdot \frac{1}{n^2} = \frac{n(n-1)}{2} \cdot \frac{1}{n^2} < \frac{1}{2} \cdot \square$$

No collisions at level 2

Corollary. The probability of no collisions is at least 1/2.

Proof. Markov's inequality says that for any nonnegative random variable *X*, we have

 $\Pr\{X \ge t\} \le E[X]/t.$

Applying this inequality with t = 1, we find that the probability of 1 or more collisions is at most 1/2.

Thus, just by testing random hash functions in H, we'll quickly find one that works.

Analysis of storage

ALGORITHMS

For the level-1 hash table *T*, choose m = n, and let n_i be random variable for the number of keys that hash to slot *i* in *T*. By using n_i^2 slots for the level-2 hash table S_i , the expected total storage required for the two-level scheme is therefore

$$E\left[\sum_{i=0}^{m-1} \Theta(n_i^2)\right] = \Theta(n),$$

since the analysis is identical to the analysis from recitation of the expected running time of bucket sort. (For a probability bound, apply Markov.)
