Approximate Program Smoothing Using Mean-Variance Statistics, with Application to Procedural Shader Bandlimiting

Y. Yang\(^1\) and C. Barnes\(^1\)

\(^1\)University of Virginia, USA

Abstract
This is a supplemental document to the paper “Approximate Program Smoothing Using Mean-Variance Statistics, with Application to Procedural Shader Bandlimiting.” We present in this supplemental document additional plots of time and error for shaders, formulas, derivations, and proofs. Note that the main paper and supplemental use a single consistent set of references.

8. Time and Error Plots for Planar Geometry
Please see Figure 7 on the next page, where we present time and error plots for all 21 shaders that were defined in the paper, applied to planar geometry.

9. Table of Smoothed Formulas
In Table 3, we show a table of functions and their corresponding convolutions with box and Gaussian kernels. These are needed for the approximations we developed in the main paper. This is a supplemental document to the paper “Approximate Program Smoothing Using Mean-Variance Statistics, with Application to Procedural Shader Bandlimiting.” We present in this supplemental document additional plots of time and error for shaders, formulas, derivations, and proofs. Note that the main paper and supplemental use a single consistent set of references.

In Table 3, we show a table of functions and their corresponding convolutions with box and Gaussian kernels. These are needed for the approximations we developed in the main paper. This table can be viewed as an extension of the table presented in Dorn et al. [DBLW15], with some errors fixed. Note that in particular, for each function \(f(x)\), we report not only the result of smoothing \(f(x)\) but also smoothing \(f^2(x)\) (e.g. if we report \(\cos(x)\)) then we also report \(\cos^2(x)\). This is needed to determine the standard deviations output by a given compute stage for the adaptive Gaussian approximation rule.

In Table 3, we give that bandlimiting \(x^n\) by a Gaussian is a generalized Hermite polynomial \(He_n^{[a]}(x)\). This can be derived from a property of generalized Hermite polynomials [Wik17]:

\[
He_n^{[a]}(x) = \sum_{k=0}^{\lfloor \frac{n}{2} \rfloor} \frac{n!}{(n-2k)!2^k} \left(-2\right)^{-k} x^{n-2k} a^k
\] (12)

10. Multivariate Smoothed Functions
In this section, we extend the analysis for the adaptive Gaussian rule from the main paper Section 4.4 to some additional multivariate functions. We explain how to derive formulas for modulo, comparisons, and a ternary selection function.

The modulo function, \(f_{\text{mod}}(a,b) = a \% b\), can be rewritten as

\[
f_{\text{mod}}(a,b) = b \cdot \text{frac}(\frac{a}{b}) \]. Here, \(\text{frac}(x)\) is the fractional part of \(x\).

We make the simplifying assumption that the second argument \(b\) of \(\text{mod}\) is an ordinary (non-random) variable (so \(\sigma_B = 0\), to obtain:

\[
\mu_{\text{mod}} = \mu_B \cdot \text{frac}(\frac{\mu_A}{\mu_B} \sigma_B^2)
\]

\[
\sigma_{\text{mod}} = \mu_B^2 \cdot \text{frac}^2(\frac{\mu_A}{\mu_B} \sigma_B^2) - \mu_{\text{mod}}^2
\] (13)

Comparison functions \((>, \geq, <, \leq)\) are approximated by converting them to univariate functions including the Heaviside step function \(H(x)\). As an example, the function greater than \((>)\) can be rewritten as \(f_>(a,b) = H(a-b)\).

One other important multi-variate function we approximated is the ternary select \((a,b,c)\) function, which returns \(b\) if \(a\) is non-zero, otherwise \(c\). We approximated this in the same manner as Dorn et al. [DBLW15] as a linear interpolation based on binary operators: select\((a,b,c) = a \cdot b + (1-a) \cdot c\).

11. Correlation Coefficients for Multivariate Functions
In this section, we describe rules to compute the correlation coefficient \(\rho\), which is briefly discussed in Section 4.4. Specifically, we are given a binary function \(f(a,b)\), which receives two inputs \(a\) and \(b\), with associated random variables \(A\) and \(B\), respectively. We discuss the following two rules: a) assume \(\rho\) is constant and estimate by sampling and b) compute \(\rho\) under the assumption that computations are affine.

Estimate \(\rho\) by sampling. In a training stage, we use \(n\) samples to approximate \(\rho\) of two random variables \(A\) and \(B\). The samples drawn from these two distributions are represented as \(a_i\) and \(b_i\) with corresponding sample mean \(\bar{a}\) and \(\bar{b}\). Thus, \(\rho\) can be estimated by:

\[
\rho = \frac{\sum_{i=1}^{n} (a_i - \bar{a})(b_i - \bar{b})}{\sqrt{\sum_{i=1}^{n} (a_i - \bar{a})^2 \sum_{i=1}^{n} (b_i - \bar{b})^2}}
\] (14)
Estimate $\rho$ by an affine assumption. When we calculate $\rho$ under this rule, we assume the variables $a$ and $b$ input to $f$ are affine transformations of the variables $x_1$, ..., $x_n$ which are input to the program. Under this assumption, $a$ and $b$ can be expressed as:

$$a = a_c + \sum_{i=1}^{n} a_i x_i, \quad b = b_c + \sum_{i=1}^{n} b_i x_i$$

(15)

In Equation (15), $a_i$ and $b_i$ are coefficients of the affine transformation, and $a_c$ and $b_c$ end up not mattering for the $\rho$ computation, so we ignore these constants. In our implementation, we find $a_i$ and $b_i$ by taking the gradient, via the automatic differentiation of the expression nodes $a$ and $b$ with respect to the inputs $x_i$. Here $\rho$ is computed as:

$$\rho = \frac{\sum_{i=1}^{n} a_i b_i}{\sqrt{\sum_{i=1}^{n} a_i^2 \sqrt{\sum_{i=1}^{n} b_i^2}}}$$

(16)

12. Smoothing Result for Periodic Functions

In this section, we derive a convenient formula that gives the bandlimited result for any periodic function if its integral within a single period is known. We extend the analysis of $\text{frac}(t)$ made by Dorn et al. [DBLW15] to any periodic function. We use Heckbert’s technique of repeated integration [Heck86] to derive the convolution of a periodic function with a box kernel.

Specifically, we assume the periodic function $f(x)$ has period $T$ and its first and second integrals within one period are also known. These are denoted as $F_p(x)$ and $F_{p2}(x)$, respectively.

$$F_p(x) = \int_{0}^{T} f(u)du$$

$$F_{p2}(x) = \int_{0}^{T} F_p(u)du$$

(17)

$x \in [0, T)$

Using Equation (17), we derive the first and second integral of $f(x)$ as follows.

$$F(x) = \int_{0}^{x} f(u)du$$

$$= \left(\frac{x}{T} + 1\right) \cdot F_p(T) - \int_{x-T}^{T} f(u)du$$

$$= \left(\frac{x}{T} + 1\right) \cdot F_p(T) - F_p(T) + F_p\left(x-T \cdot \frac{x}{T}\right)$$

(18)

$$= \left(\frac{x}{T} + 1\right) \cdot F_p(T) + F_p\left(x-T \cdot \frac{x}{T}\right)$$

submitted to EUROGRAPHICS 2018.
\[ F_2(x) = \int_0^x F(u)du = \int_0^x \left[ \frac{x}{T} \right] \cdot F_p(T)du + \int_0^x F_p(u-T \cdot \left[ \frac{x}{T} \right])du \]

\[ = F_p(T) \cdot \left[ \sum_{i=0}^{\left\lceil \frac{x}{T} \right\rceil - 1} i \cdot \left( x-T \cdot \left[ \frac{x}{T} \right] \right) \right] \cdot F_p(T) + \left[ \frac{x}{T} \right] \cdot F_{\bar{p}_2}(T) + F_{\bar{p}_2}(x-T \cdot \left[ \frac{x}{T} \right]) \]

Here, \( q = \left[ \frac{x}{T} \right] \).

Using Heckbert’s result, the convolution of the periodic function \( f(x) \) with a box kernel that has support \([−\sqrt{3}\sigma, \sqrt{3}\sigma]\) corresponding to a uniform kernel with standard deviation \( \sigma \) is:

\[ \hat{f}(x, \sigma) = \frac{F(x + \sqrt{3}\sigma) - F(x + \sqrt{3}\sigma)}{2\sqrt{3}\sigma} \]  

(20)

The convolution of the periodic function \( f(x) \) with a tent kernel that has support \([−\sqrt{6}\sigma, \sqrt{6}\sigma]\) corresponding to a uniform kernel with standard deviation \( \sigma \) is:

\[ \hat{f}(x, \sigma) = \frac{F_2(x + \sqrt{6}\sigma) - 2 \cdot F_2(x) + F_2(x - \sqrt{6}\sigma)}{6\sigma^2} \]  

(21)

13. Proof of Second Order Approximation for a Single Composition

Here we show for a univariate function, applying function composition using our adaptive Gaussian approximation from Section 4.4 is accurate up to the second order in standard deviation \( \sigma \). Suppose we wish to approximate the composition of two functions: \( f(x) = f_2(f_1(x)) \), where \( f_1, f_2 : \mathbb{R} \rightarrow \mathbb{R} \). Assume the input random variable is \( X_0 \sim N(\mu, \sigma^2) \): the Gaussian kernel centered at \( x \). The output from \( f_1 \) is an intermediate value in the computation: we can represent this with another random variable \( X_1 = f_1(X_0) \). Similarly, the output random variable \( X_2 = f_2(X_1) \). We conclude that if \( X_0 = f_2(f_1(X_0)) = f_2(X_1) = X_2 \).

We apply Equation (6) and Equation (7) to \( f_1 \), and obtain the following mean and standard deviation.

\[ \mu_{X_1} = f_1(x, \sigma^2) = f_1(x) + \frac{1}{2} \sigma^2 f_1''(x) + \mathcal{O}(\sigma^4) \]

\[ \sigma_{X_1}^2 = f_1(x, \sigma^2)^2 - f_1(x, \sigma^2)^2 + \mathcal{O}(\sigma^4) \]

Using our composition rule, \( X_1 \) is approximated as a normal distribution using the mean and standard deviation calculated from Equation (22). That is, we approximate \( X_1 \) as being distributed as \( N(\mu_{X_1}, \sigma_{X_1}^2) \). Similarly, \( \mu_{X_2} \), which is the output we care about, can be computed based on Equation (7), Equation (22), and repeated Taylor expansion in \( \sigma \) around \( \sigma = 0 \).

\[ \mu_{X_2} = f_2(f_1(x, \sigma^2), \sigma_{X_1}^2) \]

\[ = f_2(f_1(x) + \frac{1}{2} \sigma^2 f_1''(x) + \mathcal{O}(\sigma^4) + \frac{1}{2} \sigma^2 f_1''(f_1(x)) + \mathcal{O}(\sigma_{X_1}^2) \]

\[ = f_2(f_1(x) + \frac{1}{2} \sigma^2 f_1''(f_1(x)) f_1'(x) + \frac{1}{2} \sigma^2 f_1''(f_1(x)) f_1'(x) + \mathcal{O}(\sigma^4) \]  

(23)

Comparing Equation (23) with Equation (7), the function composition in our framework agrees up to the second order term in the Taylor expansion.

We conclude that our approximation is accurate up to the second order in standard deviation for a single composition of univariate functions. The same property for additional compositions of univariate functions can be shown by induction.

14. Geometry Transfer

In Figure 8, we show 6 results for geometry transfer: we tune shaders on one geometry, and use the Pareto frontier of tuned program variants to render the same shader on a different geometry. We compare the results of geometry transfer with directly training the same geometry, as is described in Section 6. We described how we choose the result of our method, Dorn et al. [DBLW15] and supersampling in Section 6.1. We then selected a result for geometry transfer that has time and error that is comparable to the directly trained result we previously selected.

References

Figure 8: Results for geometry transfer. Shaders trained on a source geometry are applied to a target geometry ("Our Transfer Results") and compared to re-training on the target geometry. Note that both transfer between curved geometries and from curved geometry to plane give good antialiasing result and have significant less error than Dorn et al. [DBLW15]. Note also that transfer results between curved geometries are typically competitive to direct training both in time and error.
Table 3: A table of univariate functions, and their corresponding bandlimited result, using a box kernel $B$ and a Gaussian $G$. The box kernel is the PDF of the uniform random variable $U[-\sqrt{3}\sigma, \sqrt{3}\sigma]$. The Gaussian kernel is the PDF of the random variable $\mathcal{N}(0, \sigma^2)$. Each random variable has standard deviation $\sigma$. We define $\text{sinc}(x) = \sin(x)/x$, and the Heaviside step function $H(x) = 0$ for $x \leq 0$ and $1$ for $x$ positive. Note that functions with undefined regions, such as $x^p$ for negative or fractional $p$ have $\sigma$ limited as described in Section 4.6.
